## **Abstract**

Topological superconductivity is a relatively fresh topic of condensed matter physics. Being a rich platform for intriguing and beautiful problems, it also has a huge and unrevealed potential for technology, especially for quantum computing.

The notion of topological superconductivity is closely related to a possibility of presence of a Majorana state — special topologically protected state, usually localized near some topological defect in a topological superconductor. Despite numerous theoretical proposals of constructing this state in condensed matter, its observation in experimental setup is still a big challenge

In this work the system of two one-dimensional superconducting wires connected with a tunnel junction is considered. Under special conditions this system can host a Majorana fermion. The properties of this system, such as subgap states, stationary supercurrent and ionization of the Majorana state under oscillating external voltage are studied. The results of this work have the potential in developing a new technique of detecting Majorana fermions in such systems.

# Chapter 1

## Introduction

The system considered in this work is a pair of 1D superconductors connected with a Josephson junction. For all the discussion presented it's crucial for one of superconductors to be topological.

Topological superconductivity is a relatively fresh topic in physics. On the one hand it's connected to particle physics through the notion of Majorana fermion – the particle coinciding with its own antiparticle [1]. It appears not only in Standard model context [2–4], but also as a state in solids [5–16]. Despite the difference between these entities, there is a clear analogy between majoranas in condensed matter and majoranas in particle physics [17, 18].

On the other hand topological superconductivity is of interest to quantum computation community as a platform to build fault tolerant quantum memory [6, 19–21]. Although significant difficulties have appeared on this way, the intention to realize this program is still strong and gives the motivation to build superconducting samples, which demonstrate signatures of nontrivial topology and presence of Majorana fermions [22–24].

The proposition of using superconducting wires as carriers of Majorana fermions came from a seminal work of Kitaev [6]. The key ingredient of this system was a p-wave superconductivity assumed to be present in a wire. It was shown, that under certain conditions the Majorana state can be present at the end of the wire. After some time other propositions [25, 26] appeared, based on semiconductor-superconductor heterostructures with s-wave superconductivity, external magnetic field and spin-orbit coupling. It was showed, that the sign of quantity  $g = B - \sqrt{\Delta^2 + \mu^2}$  (where  $B$  is magnetic field,  $\Delta$  is the absolute value of superconducting order parameter and  $\mu$  is a chemical potential) can be used as a topological index, and a Majorana state will appear where the sign of  $g$  is changing.

The model, considered in this work is close to the ones used in [25, 26]. It consists of two superconducting wires connected with a tunnel junction. However instead of domain wall of the sign of  $g$ , a tunnel barrier between areas with  $g > 0$  and  $g < 0$  is introduced. This model is formulated in detail in chapter 2. The spectrum of this model and stationary supercurrent are studied in chapter 3 and the ionization of the Majorana state under small external oscillating voltage is considered in chapter 4. Chapter 5 stands for the discussion of obtained results and their possible experimental realization, while chapter 6 concludes the study.

## Chapter 2

# The model

The model studied here is mostly inspired by the works [25] and [26] with the main difference being the presence of a tunnel contact between the wires. As will be shown in subsequent chapters, the barrier doesn't affect the appearance of Majorana state, but has important consequences for other properties of the system. In this chapter the model itself is presented.

### 2.1 Problem statement

The system under consideration consists of two 1D s-wave superconducting wires connected with a tunnel junction. There is a strong spin-orbit coupling assumed to be present and external magnetic field is applied in the direction perpendicular to the wire. The Hamiltonian of the bulk of each wire, written in the Bogoliubov-de-Gennes formalism, is similar to the ones presented in [25] and [26]:

$$\mathcal{H} = \int dy \Psi^\dagger(y) H \Psi(y) \quad \Psi = \begin{pmatrix} \psi_\uparrow \\ \psi_\downarrow \\ \psi_\downarrow^\dagger \\ -\psi_\uparrow^\dagger \end{pmatrix} \quad (2.1)$$

$$H = \left( \frac{p^2}{2m} - \mu_0 \right) \tau_z + up\sigma_z\tau_z + B\sigma_x + \Delta\tau_\phi \quad (2.2)$$

Here  $\sigma_i$  and  $\tau_i$  are Pauli matrices in spin and particle-hole subspaces respectively,  $\tau_\phi = \tau_x \cos \phi - \tau_y \sin \phi$ , with  $\phi$  being the superconducting phase,  $\mu_0$  is a chemical potential,  $B$  is an external magnetic field,  $\Delta$  is the absolute value of superconducting order parameter and  $u$  is spin-orbit coupling constant with the dimension of velocity. The wire is aligned along the y-axis, while the direction of the magnetic field coincides with x-axis. Note, that only one component of spin-orbit is nonzero due to 1D nature of the problem.

The tunnel junction is introduced by applying an external electrical field. Its potential profile  $U(y)$  is presented on figure 2.1(a). Inside each wire the potential is assumed to be homogeneous, though its value can be different to the right and to the left of the junction. The junction itself is modeled by a sharp peak of the potential.

To take this into account one should include an additional term  $U(y) \tau_z$  in (2.2). However

this term can be combined with the second term of by (2.2) by introducing an effective chemical potential  $\mu(y) = \mu_0 - U(y)$  (see figure 2.1(b)). From now on all presence of the external field will be hidden in  $\mu(y)$ .

The superconducting phase  $\phi$  in left and right wires,  $\phi_L$  and  $\phi_R$ , can also be different. The phase inside the barrier is undefined as  $\Delta(y) = 0$  there.

Figure 2.1: (a)  $y$ -profile of external electrical field. (b)  $y$ -profile of effective chemical potential

Finally, the BdG Hamiltonian for the model reads:

$$H = \left( \frac{p^2}{2m} - \mu(y) \right) \tau_z + up\sigma_z\tau_z + B\sigma_x + \Delta(y) \tau_{\phi(y)} \quad (2.3)$$

with

$$\mu(y) = \begin{cases} \mu_L, & -\frac{L}{2} < y \\ \mu_b, & -\frac{L}{2} < y < \frac{L}{2} \\ \mu_R, & \frac{L}{2} < y \end{cases} \quad \Delta(y) = \begin{cases} \Delta, & y > \frac{L}{2}, y < -\frac{L}{2} \\ 0, & -\frac{L}{2} < y < \frac{L}{2} \end{cases} \quad (2.4)$$

$$\phi(y) = \begin{cases} \phi_L, & -\frac{L}{2} < y \\ \phi_R, & \frac{L}{2} < y \end{cases} \quad (2.5)$$

with  $L$  being the size of the junction. Note, that the parameters  $B$ ,  $u$ ,  $\Delta$  and  $m$  are taken to be constant across the system.

This setup is close to one of the models considered by Oreg et al. in [25] (*"Spatially varying  $\mu$ "* section). The difference is in the profile of  $\mu(y)$  – in [25] there is a step in effective chemical potential, while here this function has a well.

In [25] it's also shown that the Majorana fermion appears at the interface between areas with different signs of the difference  $B - \sqrt{\mu^2 + \Delta^2}$ . As will be shown further, this is also relevant to

the system presented here. Note, that if  $B > |\Delta|$  this condition can always be satisfied by choosing appropriate  $\mu_L$  and  $\mu_R$ .

When two wires of different sign of  $g$  are assumed in this work, the trivial wire will always be on the left, while the topological wire will always be on the right.

The model, described by (2.3) and (2.4) possesses a big number of external parameters. Different areas in this parameter space require different approaches and sometimes lead to completely different physics. Here the certain experimentally reasonable constraints are assumed:

$$\mu_L, \mu_R \ll B \approx \Delta \ll mu^2 \ll |\mu_b| \quad (2.6)$$

The experimental justification of this choice is given in chapter 5. From the theoretical point of view the benefit of constraints  $\mu_L, \mu_R \ll B \approx \Delta \ll mu^2$  is that they make it possible to use approximate wavefunctions in the wires. The inequality  $mu^2 \ll |\mu_b|$  sets the system in the tunneling regime.

## 2.2 The dispersion of a homogeneous wire

Before discussing the properties of the junction it's necessary to consider a dispersion of a homogeneous wire modeled with the Hamiltonian (2.2). Although this can be done exactly, it's instructive to obtain this dependence step by step, starting with a simpler model and adding terms until the Hamiltonian (2.2) is restored.

The starting point is the Hamiltonian consisting only of kinetic energy and chemical potential terms:  $H = \frac{p^2}{2m} - \mu$ . It has simple parabolic dispersion presented on fig. 2.2(a). When the spin is introduced and spin-orbit coupling term  $up\sigma_z$  is added, the parabola splits in two (fig. 2.2(b)), each one corresponding to its own  $z$ -projection of the spin. After introducing a magnetic field with  $B\sigma_x$  term, the gap at the intersection opens (fig. 2.2(c)). The next step is introducing the BdG formalism, by adding the multiplier  $\tau_z$  everywhere except for magnetic field term:  $H = \left(\frac{p^2}{2m} - \mu_0\right)\tau_z + up\sigma_z\tau_z + B\sigma_x$ . This procedure doubles the spectra in a way that each eigenvector with energy  $E$  obtains a partner eigenvector with energy  $-E$ , so two additional energy branches appear, being a mirror reflection of initial dispersion. This is presented on fig. 2.2(d), with the dashed lines being BdG partners. The last step is adding the superconducting term  $\Delta\tau_\phi$ , which opens the gap where dashed and solid lines intersect (fig. 2.2(e)).

As was mentioned before, the dispersion can be found explicitly. As was pointed out in [25], it can be done by squaring the Hamiltonian (2.2) twice and solving a resulting biquadratic

equation, leading to:

$$E_{1,2}^2(p) = B^2 + \Delta^2 + \xi_p^2 + (up)^2 \pm 2\sqrt{B^2\Delta^2 + B^2\xi_p^2 + (up)^2\xi_p^2} \quad (2.7)$$

with  $\xi_p = \frac{p^2}{2m} - \mu$ . This dependence, presented on fig. 2.2(f), has two positive and two negative branches, as any BdG dispersion with electron-hole symmetry does. In further discussion only positive ( $E > 0$ ) branches are considered, if opposite is not mentioned.

Figure 2.2: The dispersion of different Hamiltonians: a) mere kinetic energy and chemical potential:  $H = \frac{p^2}{2m} - \mu$  b) spin-orbit coupling added:  $H = \frac{p^2}{2m} - \mu_0 + up\sigma_z$  c) magnetic field added:  $H = \frac{p^2}{2m} - \mu_0 + up\sigma_z + B\sigma_x$  d) BdG formalism introduced:  $H = \left(\frac{p^2}{2m} - \mu_0\right)\tau_z + up\sigma_z\tau_z + B\sigma_x$  e) The complete Hamiltonian of homogeneous wire:  $H = \left(\frac{p^2}{2m} - \mu_0\right)\tau_z + up\sigma_z\tau_z + B\sigma_x + \Delta\tau_\phi$ . The parameters of the Hamiltonians for the plotting are:  $B = 0.2$ ,  $\Delta = 0.3$ ,  $u = 0.9$ ,  $m = 1$ ,  $\mu = 0.11$

If the constrains (2.6) are assumed, the lower branch of this spectra has three minima: one of them is at  $p = 0$  exactly, and two others are at  $p = \pm 2mu$  in the leading order. The last two are not very interesting – the energy gap there is approximately equal to  $\Delta$ , as it should be due to perturbative introduction of superconducting term. On the contrary, the minimum at  $p = 0$ , which is given by[25]:

$$E_2(0) = |g|, \quad g = B - \sqrt{\Delta^2 + \mu^2} \quad (2.8)$$

is the most important peculiarity of the spectrum. First, as  $\mu \ll B \approx \Delta$ , it's the true gap of the spectrum as  $\left|B^2 - \sqrt{\Delta^2 + \mu^2}\right| \approx \left|B - \Delta - \frac{\mu^2}{2\Delta}\right| \ll \Delta$ . Second, the sign of  $g$  defines whether the wire host a Majorana state. Here it's useful to introduce the terminology: if  $g > 0$  the wire is called "topological", otherwise it's called "trivial". In [25] and [26] it was derived, that the contact

of trivial and topological wire hosts a Majorana state. It can also be shown (see section 3.5.1), that this state is present at the end of a topological wire and isn't there for a trivial one.

Note, that when two wires are considered, there are two gaps,  $g_{L,R} = B - \sqrt{\Delta^2 + \mu_{L,R}^2}$ . When the magnetic field  $B$  is close to  $\Delta$ , one can change the signs of  $g_{L,R}$  by changing  $\mu_{L,R}$  respectively.

For further discussion it's necessary to clarify the place of  $g_{L,R}$  in the parameter hierarchy of the problem. To do so, we introduce  $\beta = B - \Delta$ . As  $B \approx \Delta$ , we find that  $\beta \ll B, \Delta$ . Recalling  $\mu_{L,R} \ll B, \Delta$ , one immediately finds that  $g_{L,R} = B - \sqrt{\Delta^2 + \mu_{L,R}^2} \approx \beta - \frac{\mu_{L,R}^2}{2\Delta} \ll B, \Delta$ .

## 2.3 Short-wave and long-wave wavefunctions

Though the wavefunctions of (2.2) can be found explicitly, their form is complicated enough to stall any further analysis. However, with the parameter hierarchy introduced in the previous section the Hamiltonian (2.2) can be treated perturbatively with the following strategy.

At first step only kinetic and spin-orbit terms are left in the Hamiltonian (2.2), so

$$H \approx \left( \frac{p^2}{2m} + up\sigma_z \right) \tau_z \quad (2.9)$$

As the presence of the Majorana state depends on sign of  $g_{L,R}$ , all the topological physics appears at the energies  $E \sim g \ll mu^2$ , so the energy term can also be omitted in Schroedinger equation. This leads to a couple of solutions for the momenta:  $p_{\text{short}} \approx \pm 2mu$  and  $p_{\text{long}} \approx 0$  with a corresponding wavefunctions — short-wave and long-wave ones.

Despite the fact that all the omitted terms in (2.9) are indeed smaller than the left ones, it's can't be taken as zero order Hamiltonian — it's spectrum is ungapped, so all the solutions of Schroedinger equation are running waves and can't form a localized state. To introduce the gap one needs to add a superconducting term to (2.9). For short-wave ( $p \approx 2mu$ ) wavefunctions it's enough and is treated in section 3.3.

For long-wave wavefunctions we can't add the superconducting term without adding a magnetic term, as they both significantly alter the momenta, and, consequentially, the wavefunctions. However, for this case the kinetic term, proportional to  $p^2$ , is much smaller than the spin-orbit term and thus can be omitted. The resulting Hamiltonian is similar to the ones used in [25, 26] and treated in section 3.4.

## Chapter 3

# Stationary properties

The stationary properties of the system are defined by its spectrum. In this chapter an effective boundary condition for long-wave wave functions is introduced, wavefunctions are obtained, sub-gap states are found and the stationary supercurrent is investigated.

### 3.1 Boundary condition

To obtain the spectrum of the system it's necessary to find the wavefunctions inside the barrier. As the barrier chemical potential is the biggest energy parameter of the problem, they are defined by the Hamiltonian:

$$H(y) = \left( \frac{p^2}{2m} + \mu_b \right) \tau_z, \quad -\frac{L}{2} < y < \frac{L}{2}. \quad (3.1)$$

As low energies are the under consideration, in Schroedinger equation the energy term can be omitted, so  $p_b \approx \pm i\sqrt{2m\mu_b}$ . Matching the wavefunctions and their derivatives inside and outside the barrier, we take barrier wavefunctions out of the problem and obtain the following boundary condition for wavefunctions on the left and on the right of the barrier:

$$\begin{cases} \psi_L + b\partial_y\psi_L = t(\psi_R + b\partial_y\psi_R) \\ \psi_R - b\partial_y\psi_R = t(\psi_L - b\partial_y\psi_L) \end{cases} \quad (3.2)$$

where  $\psi_{L,R} = \psi(\mp \frac{L}{2})$ ,  $b = (2m\mu_b)^{-\frac{1}{2}} = \frac{1}{p_b}$  — the penetration depth for the particle inside the barrier and  $t = e^{-\frac{L}{b}}$  — the tunneling constant assumed to be small:  $t \ll 1$ . This condition means, that the size of the barrier  $L$  should be much bigger that the penetration depth  $b$ .

The condition (3.2) is invariant under the combined action  $L \leftrightarrow R$ ,  $y \rightarrow -y$ . To simplify further analysis we reverse the direction in the left wire and shift both ends of the wires from  $y = \frac{L}{2}$  to  $y = 0$ . The boundary condition than becomes:

$$\begin{cases} \psi_L - b\partial_y\psi_L = t(\psi_R + b\partial_y\psi_R) \\ \psi_R - b\partial_y\psi_R = t(\psi_L + b\partial_y\psi_L) \end{cases} \quad (3.3)$$

This transformation is illustrated on fig. 3.1. Note

The boundary condition (3.3) can be rewritten with the spinor  $\Psi = (\psi_L, \psi_R)^T$  and Pauli matrices  $\hat{s}_i$  in LR space:

$$(1 - t\hat{s}_x) \Psi - (1 + t\hat{s}_x) b\partial_y \psi = 0 \quad (3.4)$$

Since for all  $t \neq 1$  (recall, that  $t \ll 1$ ) the matrix is  $1 \pm t\hat{s}_x$  in invertible multiplying the last equation by  $(1 - t\hat{s}_x) / (1 + t^2)$  yields:

$$(1 - 2\tilde{t}\hat{s}_z - \tilde{b}\partial_y) \Psi = 0 \quad (3.5)$$

where  $\tilde{t} = \frac{t}{1+t^2}$ ,  $\tilde{b} = \frac{1-t^2}{1+t^2}b$ . In the leading order in  $t$ , which corresponds to the tunneling limit,  $\tilde{t} = t$ ,  $\tilde{b} = b$ .

Figure 3.1: Illustration of switching the direction of left wire

One can argue that in tunneling limit the second and the third term in (3.5) are much smaller than the first one and should not be taken when the leading order is considered. However, if the second term is omitted, the wires become disconnected, and no tunnel effects can be found. The same is true for the third term — if it's not present, the boundary condition immediately implies  $\Psi(0) = 0$ , so the wires become disconnected again.

## 3.2 Short-wave wavefunctions

As was pointed in section 2.3, the short-wave wavefunctions should be described with the Hamiltonian (2.9) with a superconducting term:

$$H = \left( \frac{p^2}{2m} - up\hat{s}_z\sigma_z \right) \tau_z + \Delta\tau_\phi \quad (3.6)$$

here the multiplier  $\hat{s}_z$  is added in the spin-orbit coupling term, as the direction of the left wire is inverted, so to write a correct Hamiltonian for LR space, one needs to change  $p$  to  $-p$  for the left wire — which is adding  $-\hat{s}_z$  multiplier to each momentum.

Denoting  $\eta = \frac{p^2}{2m} - up\hat{s}_z\sigma_z$ , one can rewrite (3.6) as  $H = \eta\tau_z + \Delta\tau_\phi$ . As  $\hat{s}_z\sigma_z$  commutes

with  $H$  one can treat it as a number, so the dispersion is  $E^2 = \eta^2 + \Delta^2$  (the number corresponding to eigenstate of  $\hat{s}_z$  will be denoted as  $s_z$  while the number, corresponding to the eigenstate of  $\sigma_z$  will be denoted as  $\varsigma_z$ ). Thus  $\eta = \pm i\sqrt{\Delta^2 - E^2}$ , as the case  $|E| < \Delta$  is assumed. For momenta one can write the equation:

$$p^2 - 2mus_z\varsigma_z p - 2m\eta = 0 \quad (3.7)$$

which for short-wave momenta gives  $p_{\text{short}} \approx 2mus_z\varsigma_z + \frac{\eta}{u}s_z\varsigma_z$ . Choosing the sign of  $\eta$  in a way, that the wavefunction decays at  $x \rightarrow +\infty$ , we obtain:

$$p_{\text{short}} \approx 2mus_z\varsigma_z + i\frac{\sqrt{\Delta^2 - E^2}}{u} \quad (3.8)$$

Now the wavefunction can be constructed by putting (3.8) into the Schroedinger equation  $(\eta\tau_z + \Delta\tau_\phi)\Psi = E\Psi$ . The solutions are:

$$\Psi_{s_z, \varsigma_z}(x) = \begin{pmatrix} 1 \\ e^{i(s_z\varsigma_z\gamma + \phi_{s_z})} \end{pmatrix}_{eh} e^{2imus_z\varsigma_z x - \frac{\sqrt{\Delta^2 - E^2}}{u}x} |s_z, \varsigma_z\rangle \quad (3.9)$$

where  $|s_z, \sigma_z\rangle$  are eigenvectors of  $\hat{s}_z\sigma_z$ ,  $\gamma = -\frac{\pi}{2} + \arcsin \frac{E}{\Delta}$  and  $\phi_1 = \phi_L$ ,  $\phi_{-1} = -\phi_R$ . Thus the long-wave part the wavefunction can be written as:

$$\Psi_{\text{short}} = \sum_{s_z=\pm 1} \sum_{\varsigma_z=\pm 1} C_{s_z, \varsigma_z} \Psi_{s_z, \varsigma_z}(x) \quad (3.10)$$

### 3.3 Eliminating short-wave wavefunctions from boundary condition

As the Majorana state lives at low energies, it's expected to be predominantly long-wave. This argument is in accord with [25] and [26], where the Majorana state was an eigenstate of a linearized Hamiltonian, which is relevant only for long-wave physics. So, it's reasonable to eliminate the short-wave components from the problem, reformulating the boundary condition (2.9).

The wave function can be decomposed in short-wave and long-wave parts:  $\Psi = \Psi_{\text{short}} + \Psi_{\text{long}}$ . Inserting it into (2.9) and using the fact, that  $p_{\text{long}} \ll p_{\text{short}} \approx 2mus_z\sigma_z$ , one can obtain at the boundary:

$$(1 - 2t\hat{s}_x)\Psi_{\text{long}} + (1 - 2t\hat{s}_x - 2ibum\hat{s}_z\sigma_z)\Psi_{\text{short}} = 0 \quad (3.11)$$

Multiplying by the  $(1 - 2t\hat{s}_x)^{-1}$  and omitting  $t^2$  terms, we obtain:

$$\Psi_{\text{long}} = (-1 + i\zeta(1 + 2t\hat{s}_x)s_z\sigma_z)\Psi_{\text{short}} \quad (3.12)$$

with  $\zeta = 2bum$ .

Now, using the expansion (3.10) and renormalizing the coefficients:  $C_{s_z\varsigma_z} \rightarrow -(1 - i\zeta s_z\varsigma_z)C_{s_z\varsigma_z}$  one can rewrite the boundary condition for  $\varsigma_z$  spin component of the wavefunction as:

$$\Psi_{\text{long},\varsigma_z} = \left(1 + \frac{2i\zeta t\hat{s}_z\sigma_z}{1 + i\zeta\hat{s}_z\sigma_z}\right) \sum_{s_z=\pm 1} C_{s_z,\varsigma_z} \begin{pmatrix} 1 \\ e^{i(s_z\varsigma_z\gamma+\phi_{s_z})} \end{pmatrix}_{eh} e^{2imus_z\varsigma_z x - \frac{\sqrt{\Delta^2 - E^2}}{u}x} |s_z, \varsigma_z\rangle \quad (3.13)$$

This can be multiplied by  $\left(1 + \frac{2i\zeta t\hat{s}_z\sigma_z}{1 + i\zeta\hat{s}_z\sigma_z}\right)^{-1}$ , which up to a  $t^2$  correction yields:

$$\left(1 - \frac{2i\zeta t\hat{s}_z\sigma_z}{1 + i\zeta\hat{s}_z\sigma_z}\right) \Psi_{\text{long},\varsigma_z} = \sum_{s_z=\pm 1} C_{s_z,\varsigma_z} \begin{pmatrix} 1 \\ e^{i(s_z\varsigma_z\gamma+\phi_{s_z})} \end{pmatrix}_{eh} e^{2imus_z\varsigma_z x - \frac{\sqrt{\Delta^2 - E^2}}{u}x} |s_z, \varsigma_z\rangle \quad (3.14)$$

For each  $\varsigma_z$  the above equation can be interpreted as the requirement that the l.h.s. 4-vector (in LR- and eh-spaces) lies in the 2d linear space  $L_2$  spanned by the two vectors in the sum in the r.h.s.. This can be reformulated as the requirement that the l.h.s. be orthogonal to the complementary 2d space  $\bar{L}_2$ . There are two basic vectors  $\bar{\Psi}_{s_z\varsigma_z}$  ( $s_z = \pm 1$ ) spanning  $\bar{L}_2$  for each  $\varsigma_z$ :

$$\bar{\Psi}_{s_z\varsigma_z} = \begin{pmatrix} 1 \\ -e^{i(s_z\varsigma_z\gamma+\phi_{s_z})} \end{pmatrix} |s_z, \varsigma_z\rangle \quad (3.15)$$

Thus one needs to multiply (3.14) by  $(\bar{\Psi}_{+\varsigma_z}^T, \bar{\Psi}_{-\varsigma_z}^T)$  from the left and, after all evaluating the matrix product, find the effective boundary condition for long-wave wavefunctions in the form:

$$\begin{pmatrix} 1 & -e^{-i(\varsigma_z\gamma-\phi_L)} & A & -Ae^{-i(\varsigma_z\gamma-\phi_L)} \\ A^* & -A^*e^{i(\varsigma_z\gamma+\phi_R)} & 1 & -e^{i(\varsigma_z\gamma+\phi_R)} \end{pmatrix} \Psi_{\text{long},\varsigma_z} = 0 \quad (3.16)$$

here  $A = -\frac{2i\zeta t\varsigma_z}{1+i\zeta\varsigma_z}$  and the elements are ordered as  $(Le, Lh, Re, Rh)$ .

When studying wavefunctions in superconductors, it is more convenient to work with zero phase  $\phi$ . This can be achieved by gauging the phase difference into the boundary condition. Indeed, suppose  $H_\phi$  describes a wire with phase  $\phi$ . Then,  $H_\phi = U_\phi^\dagger H_0 U_\phi$  with  $U_\phi = e^{-\frac{i\tau_z\phi}{2}}$  and the wave functions are also related via unitary rotation  $\psi_\phi = U_\phi^\dagger \tilde{\psi}$ . So the transform  $\hat{U} = \text{diag}(U_{\phi_L}, U_{\phi_R})_{L,R}$  will eliminate all the phases from the wires and put them into the boundary condition. Substituting  $\Psi_{\text{long},\varsigma_z} = U^\dagger \tilde{\Psi}$  into (3.16) one arrives at an even simpler boundary condition on the zero-phase

function  $\tilde{\Psi}$ :

$$\begin{pmatrix} 1 & -e^{-i\varsigma_z\gamma} & A & -Ae^{-i(\varsigma_z\gamma+\varphi)} \\ A^* & -A^*e^{i(\varsigma_z\gamma+\varphi)} & 1 & -e^{i\varsigma_z\gamma} \end{pmatrix} \tilde{\Psi}_{\text{long},\varsigma_z} = 0 \quad (3.17)$$

where  $\varphi = \phi_R - \phi_L$ . Note, that any physical quantity can depend only on phase difference  $\varphi$ , but not on  $\phi_L$  or  $\phi_R$  separately.

It's also convenient to rewrite it in the form acting on the left and right wire wavefunctions:

$$M_L \tilde{\psi}_{\text{long}}^L + M_R \tilde{\psi}_{\text{long}}^R = 0$$

$$M_L = \begin{pmatrix} 1 & -e^{-i\sigma_z\gamma} \\ A^* & -A^*e^{i(\sigma_z\gamma+\varphi)} \end{pmatrix}_{eh} \quad M_R = \begin{pmatrix} A & -Ae^{i(\sigma_z\gamma+\varphi)} \\ 1 & -e^{i\sigma_z\gamma} \end{pmatrix}_{eh} \quad (3.18)$$

This form is especially useful for finding subgap states localized near the barrier.

### 3.4 Low momenta and linearized Hamiltonian

To utilize boundary condition (3.16) or (3.17), it's necessary to find low momenta wavefunctions in homogeneous wire (this functions constitute  $\psi_{\text{long}}$  in (3.16) and (3.17). As was pointed in section 2.3, for this purpose one can use the linearized version of the Hamiltonian (2.2), like in [25] and [26]:

$$H = -\mu\tau_z + up\sigma_z\tau_z + B\sigma_x + \Delta\tau_x \quad (3.19)$$

here zero phase  $\phi$  is assumed and  $\mu$  is equal  $\mu_L$  or  $\mu_R$  depending on the wire considered. As was mentioned before, a nonzero phase can be restored by using  $U_\phi$  matrix. This Hamiltonian is valid only for the right wire. To obtain the solution in the left wire one needs to reverse the sign of  $p$  in (2.2). Instead of doing so, the unitary transform  $\psi_L = \sigma_x\psi_R$  can be utilized, as  $H(-p) = \sigma_x H(p) \sigma_x$ .

Remembering, that  $\beta = B - \Delta \ll B, \Delta$ , one can treat this Hamiltonian perturbatively and decompose it as  $H = H_0 + V_0$ :

$$H_0 = up\sigma_z\tau_z + \Delta(\sigma_x + \tau_x) \quad (3.20)$$

$$V = -\mu\tau_z + \beta\sigma_x \quad (3.21)$$

As  $H_0$  commutes with  $\sigma_x\tau_x$ , it's convenient to rewrite it in the basis of common eigenstates

of  $\sigma_x$  and  $\tau_x$ . Denoting them as  $|\sigma_x, \tau_x\rangle$  and arranging the order as  $(|+, +\rangle, |-, -\rangle, |+, -\rangle, |-, +\rangle)$  one can rewrite  $H_0 + V$  as:

$$H_0 = \begin{pmatrix} 2\Delta & up & 0 & 0 \\ up & -2\Delta & 0 & 0 \\ 0 & 0 & 0 & up \\ 0 & 0 & up & 0 \end{pmatrix}, \quad V = \begin{pmatrix} \beta & 0 & -\mu & 0 \\ 0 & -\beta & 0 & -\mu \\ -\mu & 0 & \beta & 0 \\ 0 & -\mu & 0 & -\beta \end{pmatrix} \quad (3.22)$$

It's easy to see, that the wavefunctions from the subspace  $\text{Span}(|+, +\rangle, |-, -\rangle)$  (we denote them as  $\psi_{\text{medium}}$ ) require no perturbation to obtain the eigenstates in the leading order. Indeed, diagonalizing the upper subblock of  $H_0$ , one finds, that  $E = \sqrt{(2\Delta)^2 + (up)^2}$ . When the low energy states are the objects of interest ( $E \sim g_{L,R}$ ), one finds, that  $p = \pm \frac{i\Delta}{2u}$  in the leading order, and the corresponding wavefunctions are  $|+, +\rangle \pm i|-, -\rangle$ .

The other two eigenstates (we denote them as  $\psi_{\text{longest}}$ ) are a little bit more complicated. Diagonalizing the lower subblock of  $H_0$ , one immediately finds, that  $E = \pm up$ . This corresponds to the fact, that  $H_0$  is the version of  $H$  with a closed gap  $g$  on lower branch (see fig. 2.2,(e)), so in the zeroth order these states cannot form anything localized at all. To find them correctly, one needs to take into account the perturbation  $V$  and solve the secular equation using the following ansatz:

$$\psi = r_1 |+, +\rangle + r_2 |-, -\rangle + q_1 |+, -\rangle + q_2 |-, +\rangle \quad (3.23)$$

with  $r_i \ll q_j$  for all pairs  $(i, j)$ . In the leading order (remember, that both  $E$  and  $up$  are of the order of  $g_{L,R}$  now) this results in a couple of equations:

$$\begin{cases} \left(-E + B - \Delta - \frac{\mu^2}{2\Delta}\right) q_1 + upq_2 = 0 \\ upq_1 + \left(-E - B + \Delta + \frac{\mu^2}{2\Delta}\right) q_2 = 0 \end{cases} \quad (3.24)$$

recall, that  $g = B - \Delta - \frac{\mu^2}{2\Delta}$  and find  $E^2 = g^2 + u^2p^2$ .

Now it's time to present these wavefunctions in original BdG basis. The expressions here are relevant only for the right wire and for  $E > 0$ . To find the wavefunctions in the left wire, the transform  $\psi_L = \sigma_x \psi_R$  is used, while for finding the negative energy states we utilize electron-hole transform:  $\psi_{E<0} = \tau_y \sigma_y K \psi_{E>0}$  with  $K$  being a complex conjugation operator.

For  $E > 2\Delta$  wavefunctions  $\psi_{\text{medium}}$  are:

$$\psi_{\text{medium}}^{\text{out, in}} \Big|_{E > 2\Delta} = \begin{pmatrix} 1 \\ \frac{E \mp \sqrt{E^2 - 4\Delta^2}}{2\Delta} \\ \frac{E \mp \sqrt{E^2 - 4\Delta^2}}{2\Delta} \\ 1 \end{pmatrix} e^{\frac{\pm ix \sqrt{E^2 - 4\Delta^2}}{u}} \quad (3.25)$$

For  $E < 2\Delta$  wavefunctions  $\psi_{\text{medium}}$  are

$$\psi_{\text{medium}}^{\text{grow, dec}} \Big|_{E < 2\Delta} = \begin{pmatrix} 1 \\ \frac{E \pm i \sqrt{4\Delta^2 - E^2}}{2\Delta} \\ \frac{E \pm i \sqrt{4\Delta^2 - E^2}}{2\Delta} \\ 1 \end{pmatrix} e^{\frac{\pm x \sqrt{4\Delta^2 - E^2}}{u}} \quad (3.26)$$

For  $E > |g|$  wavefunctions  $\psi_{\text{longest}}$  are:

$$\psi_{\text{longest}}^{\text{out, in}} \Big|_{E > g} = \begin{pmatrix} 1 \\ \frac{E \mp \sqrt{E^2 - g^2}}{g} \\ -\frac{E \mp \sqrt{E^2 - g^2}}{g} \\ -1 \end{pmatrix} e^{\pm \frac{ix \sqrt{E^2 - g^2}}{u}} \quad (3.27)$$

For  $E < |g|$  wavefunctions  $\psi_{\text{longest}}$  are:

$$\psi_{\text{longest}}^{\text{grow, dec}} \Big|_{E < g} = \begin{pmatrix} 1 \\ \frac{E \pm i \sqrt{g^2 - E^2}}{g} \\ -\frac{E \pm i \sqrt{g^2 - E^2}}{g} \\ -1 \end{pmatrix} e^{\pm \frac{x \sqrt{g^2 - E^2}}{u}} \quad (3.28)$$

### 3.5 Subgap states

To find the bound states one needs to make two linear combinations (each for it's own wire) of decaying wave functions from (3.26) and (3.28) at  $x = 0$  and put them into boundary condition (3.3). For the right wire they can be taken directly from (3.26), (3.28), while for the left wire they should be multiplied by  $\sigma_x$  from the left (see the beginning of section 3.4).. These linear combinations can be written as:

$$\tilde{\psi}_L = C_{\text{medium}}^L \sigma_x \psi_{\text{medium}}^{\text{dec}} + C_{\text{longest}}^L \sigma_x \psi_{\text{longest}}^{\text{dec}} \quad \tilde{\psi}_R = C_{\text{medium}}^R \psi_{\text{medium}}^{\text{dec}} + C_{\text{longest}}^R \psi_{\text{longest}}^{\text{dec}} \quad (3.29)$$

where  $C_{\text{medium}}^L$ ,  $C_{\text{longest}}^L$ ,  $C_{\text{medium}}^R$ ,  $C_{\text{longest}}^R$  are the undefined coefficients. Note, that the spinor  $\psi_{\text{medium}}^{\text{dec}}$  is the same for the left and for the right wires.

Putting these combinations into boundary condition (3.3), we obtain four equations for these coefficients. If this system has a non-trivial solution at energy  $E_0$ , than there is a bound state with this energy. The condition of solvability can be written as:

$$\det F = 0 \quad (3.30)$$

where matrix  $F$  is given by:

$$F = \begin{pmatrix} M_L \sigma_x \psi_{\text{medium}}^{\text{dec}}, & M_L \sigma_x \psi_{\text{longest}}^{\text{dec}} & M_R \psi_{\text{medium}}^{\text{dec}}, & M_R \psi_{\text{longest}}^{\text{dec}} \end{pmatrix} \quad (3.31)$$

As  $E \sim g_{L,R} \ll \Delta$ , the medium-wave spinor can be taken in its low-energy form: In most of this work the low energy version  $\psi_{\text{medium}}^{\text{dec}} \approx (1, -i, -i, 1)^T$  will be sufficient.

For dealing with  $\psi_{\text{longest}}^{\text{dec}}$  it's convenient to introduce two quantities  $\chi_{L,R}$ :

$$\cosh \chi_{L,R} = \frac{g_{L,R}}{\sqrt{g_{L,R}^2 - E^2}} \quad \sinh \chi_{L,R} = \frac{E}{\sqrt{g_{L,R}^2 - E^2}} \quad (3.32)$$

If  $g > 0$ , the corresponding parameter  $\chi$  is real and monotonously growing with  $E$ . For  $g < 0$  the parameter  $\chi$  is complex, but can be written as  $\chi = -\tilde{\chi} + i\pi$  with real and monotonous  $\tilde{\chi}$ .

With these parameters the spinors  $\psi_{L(R),\text{longest}}^{\text{dec}}$  at  $x = 0$  can be written as:

$$\psi_{L(R),\text{longest}}^{\text{dec}} = \begin{pmatrix} -\sinh \chi_{L(R)} - i \\ -\cosh \chi_{L(R)} \\ \cosh \chi_{L(R)} \\ \sinh \chi_{L(R)} + i \end{pmatrix} \quad (3.33)$$

This parametrization completes the toolset used for studying the subgap spectrum.

### 3.5.1 The case of zero tunneling

Consider first equation (3.30) with  $t = 0$ . This corresponds to absolutely unpenetrable barrier, or, which is same, to independent wires ended with a vacuum. The computation of the determinant in (3.30) becomes a rather easy problem and results in:

$$\det F \Big|_{t=0} = -16 (i \sinh(\chi_L) + \cosh(\chi_L) - 1) (i \sinh(\chi_R) + \cosh(\chi_R) - 1) \quad (3.34)$$

If both  $g_L, g_R$  are negative (triv-triv junction), this determinant cannot be equal to zero at all, as  $\cosh \chi_{L,R}$  are also negative and the real part in each bracket always non zero. If one of  $g_L, g_R$  (triv-top junction), say  $g_R$ , there is only one solution at  $E = 0$ . If both  $g_L, g_R$  (top-top junction) are positive, there are two solutions at  $E = 0$ .

This result proves, that the presence of Majorana mode in a isolated wire is defined only by the sign of  $g$  and justifies the notion of topology in this system.

### 3.5.2 Weak tunneling

To take into account the tunneling effect one may expand  $\det F$  in  $t$ . Note, that there is no first order in  $t$  due to the structure of boundary condition (3.17). The decomposition can be written as:

$$\det F = d_0 + d_2 t^2 + \dots \quad (3.35)$$

where  $d_0$  is given by (3.34).  $d_2$  can be computed in a same way, but appears to be a rather complex formula. However, in tunneling limit the second term in (3.35) is small, so the only values of  $E$  that should be considered are the ones where  $d_0$  is close to zero.

For triv-triv junction there are no such points, so in the tunneling limit there are no bound states for this case.

For triv-top junction there is a solution for  $E = 0$ , which corresponds to  $\chi_L = i\pi, \chi_R = 0$ . Computing  $d_2$  for this parameters, one finds that it's exactly zero, so there is no correction to Majorana energy — as it should be, as it's protected by a particle-hole symmetry. This solution with the first correction in  $t$  is presented in appendix A.

For top-top junction the situation is more interesting. In that case there are two solutions at  $E = 0$ , which should split for nonzero  $t$ . Calculating  $d_2$  at  $E = 0$  and expanding  $d_0$  for small  $E$ , one finds:

$$d_0 = \frac{16E^2}{g_R g_L} \quad d_2 = -\frac{256t^2 \zeta^4}{(1 + \zeta^2)^2} \cos^2 \frac{\phi}{2} \quad (3.36)$$

Using, that  $\zeta = 2bum \ll 1$ , one can find the energy levels:

$$E_{1,2} = \pm 4t \zeta^2 \sqrt{g_R g_L} \cos \frac{\phi}{2} \quad (3.37)$$

this answer is relevant only if these level are well below the gaps:  $t \zeta^2 \sqrt{g_R g_L} \ll \min [g_R, g_L]$ .

### 3.6 Stationary supercurrent

The stationary supercurrent for a Josephson contact is given by [27]:

$$I = -\frac{2e}{\hbar} \sum_p \tanh\left(\frac{\epsilon_p}{2k_B T}\right) \frac{d\epsilon_p}{d\varphi} - \frac{4e}{\hbar} k_B T \int_{cont.} d\epsilon \log\left[2 \cosh\left(\frac{\epsilon}{2k_B T}\right)\right] \frac{d\rho}{d\varphi} + \frac{2e}{\hbar} \frac{d}{d\varphi} \int dy \frac{|\Delta|^2}{|c|} \quad (3.38)$$

Here  $\epsilon_p$  are the energies of the states localized near the barrier,  $\rho$  is the density of states and  $c(\mathbf{r})$  is the interaction constant of the BCS theory,  $\varphi$  is a phase difference,  $k_B$  is Boltzmann's constant and  $T$  is the temperature. The first term comes from the discrete spectrum and the sum is taken over all states in it, the second term is the current from continuous spectra and the third term comes from inhomogeneity of the order parameter. As pointed in [27], despite being generally nonzero, this last term doesn't contribute when step-model functions  $\Delta$  like in (2.4) are used. The applicability of this approximation is a direct consequence of the tunneling regime considered in this work.

After omitting the third term and taking the low temperature limit one rewrites (3.38) as:

$$I = -\frac{2e}{\hbar} \sum_p \frac{d\epsilon_p}{d\varphi} - \frac{2e}{\hbar} \int_{cont.} \epsilon d\epsilon \frac{d\rho}{d\varphi} \quad (3.39)$$

As was shown in section 3.5, there are no subgap states in triv-top contact except Majorana state. But this state lies exactly at zero energy regardless of the phase difference, so the derivative in the first term of (3.39) will be zero and no supercurrent from the Majorana state is present.

To find the current from the continuous spectrum with (3.39) one needs to know the density of states. As there is a derivative over  $\varphi$  taken, one need to find the phase dependent part of  $\rho$  only. It can be done by using the relation between the density of states and the scattering matrix [28]:

$$\rho(\phi) = \frac{1}{2\pi i} \frac{\partial}{\partial \epsilon} \log \det \hat{S} + const. \quad (3.40)$$

The  $s$ -matrix connects the coefficients between the wavefunctions going to barrier and from it. It can be obtained with the help of wavefunctions (3.26), (3.25), (3.28) and (3.27) and boundary condition (3.3). To deal with radicals some additional parameters are used. When the given wavefunction is localized ( $E < g$ ),  $\theta$ -parametrization is used:

$$\theta_{L,R} : \quad \sin \theta_{L,R} = \frac{E}{g_{L,R}}, \quad \cos \theta_{L,R} > 0 \quad (3.41)$$

this parametrization is useful for both trivial and topological wires. When the wavefunction propagates ( $E > g$ ), the  $\eta$ - or  $\kappa$ -parametrization is used, depending on the sign of  $g$ :

$$\eta_R : \cosh \eta_R = \frac{E}{g_R}, \quad \sinh \eta_R > 0 \quad \kappa_L : \cosh \kappa_L = \frac{E}{|g_L|}, \quad \sinh \kappa_L > 0 \quad (3.42)$$

To keep all the parameters real,  $\eta$  will be used for a topological wire, whereas  $\kappa$  will be used for a trivial wire. All the parameters  $\theta_{L,R}$ ,  $\kappa_L$  and  $\eta_R$  are always real and positive when used.

As the dimension of  $s$ -matrix depends on the number of propagating modes, and thus on the energy, it's necessary to investigate different energy ranges separately.

For  $E \ll \Delta$  one may use low energy limit of functions  $\psi_{\text{medium}}^{\text{dec}} : \psi_{\text{medium}}^{\text{dec}} \approx (1, -i, -i, 1)^T e^{-\frac{2\Delta x}{u}}$  and also set  $\gamma = -\frac{\pi}{2} \arcsin \frac{E}{\Delta} \approx -\frac{\pi}{2}$ . When  $E \sim \Delta$  one has to use  $\gamma$  as it is, and high energy of  $\psi_{\text{longest}}^{\text{dec}} : \psi_{\text{longest}}^{\text{dec}} \approx (1, 0, 0, 1)^T e^{-\frac{Ex}{u}}$ .

The eigenstates for the system at energies near  $g$  are presented in appendix A, in leading and subleading order on  $t$ . Here we focus on the result for the supercurrent in different cases.

### 3.6.1 Supercurrent for $E$ between $|g_L|$ and $g_R$

Recall, that the trivial wire is placed on the left while the topological wire is on the right. There are two slightly distinct cases, which differ by relation between  $g_L$  and  $g_R$ .

**The case  $|g_L| > g_R$**

For  $g_R < E < |g_L|$  there is only one state which goes towards the barrier, so the  $s$ -matrix has the dimension 1, and thus its determinant coincides with its only matrix element. The determinant which reads:

$$\det \hat{S} = -\frac{e^{\eta_R} + i}{1 + ie^{\eta_R}} - \frac{2i\zeta^4 t^2 e^{-i\varphi} (1 + e^{i\varphi})^2 (-1 + e^{i\theta_L}) (e^{2\eta_R} - 1)}{(\zeta^2 + 1)^2 (1 + e^{i\theta_L}) (e^{\eta_R} - i)^2} + O(t^4) \quad (3.43)$$

Using (3.39) (3.40), one finds, that:

$$I = \frac{8e}{\pi\hbar} t^2 \zeta^4 \sin \varphi \left( \sqrt{g_L^2 - g_R^2} - \int_{g_R}^{|g_L|} dE \frac{\sqrt{E^2 - g_R^2}}{\sqrt{1 - \frac{E^2}{g_L^2} + 1}} \right) \quad (3.44)$$

It's easy to see, that  $I \lesssim \frac{8e}{\pi\hbar} t^2 \zeta^4 g_R \sin \varphi$ .

**The case**  $|g_L| < g_R$

For  $|g_L| < E < g_R$  the  $s$ -matrix (and its determinant) is:

$$\det \hat{S} = \frac{e^{\kappa_L} - i}{-1 + ie^{\kappa_L}} - \frac{2i\zeta^4 t^2 e^{-i\varphi} (1 + e^{i\varphi})^2 (e^{2\kappa_L} - 1) (1 + e^{i\theta_R})}{(\zeta^2 + 1)^2 (e^{\kappa_L} + i)^2 (-1 + e^{i\theta_R})} + O(t^4) \quad (3.45)$$

Again with the help of (3.39) (3.40), one finds, that:

$$I = \frac{8e}{\pi\hbar} t^2 \zeta^4 \sin \varphi \left( \sqrt{g_R^2 - g_L^2} - g_R \int_{|g_L|}^{g_R} \frac{dE}{E^2} \sqrt{E^2 - g_L^2} \left( \sqrt{1 - \frac{E^2}{g_R^2}} + 1 \right) \right) \quad (3.46)$$

The estimate for this case is  $I \lesssim \frac{8e}{\pi\hbar} t^2 \zeta^4 |g_L| \sin \varphi$ .

### 3.6.2 Supercurrent for $|g_L|, g_R < E \ll \Delta$

In this case there are to states propagating towards the barrier – one in the right wire and one in the left, so the  $s$ -matrix is 2x2. Arranging its elements in the following order:

$$\hat{S} = \begin{pmatrix} r_{LL} & t_{LR} \\ t_{RL} & r_{RR} \end{pmatrix} \quad (3.47)$$

we find:

$$r_{LL} = \frac{e^{\kappa_L} - i}{-1 + ie^{\kappa_L}} + \frac{2\zeta^4 t^2 e^{-i\varphi} (1 + e^{i\varphi})^2 (e^{2\kappa_L} - 1) (e^{\eta_R} + i)}{(\zeta^2 + 1)^2 (e^{\kappa_L} + i)^2 (-1 - ie^{\eta_R})} + O(t^4) \quad (3.48)$$

$$r_{RR} = -\frac{e^{\eta_R} + i}{1 + ie^{\eta_R}} + \frac{2\zeta^4 t^2 e^{-i\varphi} (1 + e^{i\varphi})^2 (e^{\kappa_L} - i) (e^{2\eta_R} - 1)}{(\zeta^2 + 1)^2 (-1 + ie^{\kappa_L}) (e^{\eta_R} - i)^2} + O(t^4) \quad (3.49)$$

$$t_{LR} = \frac{2\zeta^2 t e^{-i\varphi} (1 + e^{i\varphi}) \sqrt{(e^{2\kappa_L} - 1) (e^{2\eta_R} - 1)}}{(\zeta^2 + 1) (e^{\kappa_L} + i) (e^{\eta_R} - i)} + O(t^3) \quad (3.50)$$

$$t_{RL} = -\frac{2t\zeta^2 (1 + e^{i\varphi}) \sqrt{(e^{2\kappa_L} - 1) (e^{2\eta_R} - 1)}}{(\zeta^2 + 1) (e^{\kappa_L} + i) (e^{\eta_R} - i)} + O(t^3) \quad (3.51)$$

The computation of supercurrent is again made with (3.39) (3.40). Introducing  $g_{\max} = \max[g_R, |g_L|]$ ,  $g_{\min} = \min[g_R, |g_L|]$  and

$$s_g = \begin{cases} 1, & g_R > |g_L| \\ -1, & g_R < |g_L| \end{cases} \quad (3.52)$$

one finds:

$$I = \frac{8e}{\pi\hbar} t^2 \zeta^4 \sin \varphi \left( s_g \sqrt{g_{\max}^2 - g_{\min}^2} - g_R |g_L| \int_{g_{\max}}^{\Delta} \frac{dE}{E^2} \left( \frac{\sqrt{E^2 - g_R^2}}{g_R} - \frac{\sqrt{E^2 - g_L^2}}{|g_L|} \right) \right) \quad (3.53)$$

It's important to note, that this computation is irrelevant for  $E \sim \Delta$ , so  $\Delta$  here acts like high energy cutoff. However the current from these states can be estimated as

$$I \sim \frac{8e}{\pi\hbar} t^2 \zeta^4 g_{\max} \log \left( \frac{\Delta}{g_{\max}} \right) \sin \varphi \quad (3.54)$$

### 3.6.3 Supercurrent for $|g_L|, g_R \ll E \lesssim \Delta$

To make the estimate for the supercurrent at energies  $E \lesssim \Delta$  high energy limits of  $\psi_{\text{longest}}$  can be used, so the system "forgets" about  $g_L$  and  $g_R$  and becomes effectively symmetric. Taking the notation from (3.47), we find:

$$r_{LL} = r_{RR} = e^{i\gamma} + \zeta^2 t^2 e^{-i\varphi} \left( \frac{(-1 + e^{2i\gamma})^2 (1 + e^{i\varphi})^2}{e^{i\vartheta} - e^{i\gamma}} + 2e^{i\gamma} (e^{2i(\gamma+\varphi)} + e^{2i\gamma} - 2e^{i\varphi}) \right) + O(t^4) \quad (3.55)$$

$$t_{RL} = -t_{RL} = i\zeta t (1 + e^{2i\gamma}) (-1 + e^{i\varphi}) + O(t^3) \quad (3.56)$$

where  $\cos \vartheta = \frac{E}{2\Delta}$ ,  $\sin \vartheta > 0$ . Using (3.39) (3.40), we find:

$$I \sim \frac{e}{\hbar} \zeta^2 t^2 \Delta \sin \varphi. \quad (3.57)$$

### 3.6.4 Analyzing the results

From the estimates below (3.46) and (3.44) one may see, that the current coming from the states between  $g_L$  and  $g_R$  has a multiplier of the order  $g_R$  or  $|g_L|$ . The current from the states above  $g_{\max}$  and near it can be estimated with (3.54). It has the multiplier  $g_{\max} \log \frac{\Delta}{g_{\max}}$ . Finally, according to (3.57), the current from the states near  $\Delta$  is proportional to  $\Delta$ . Thus we deduce that the current from the low energy states is negligible compared with the current from the states near  $\Delta$ .

This shows us that the low energy states ( $E \ll \Delta$ ) contribute to stationary supercurrent by a very small quantity. The proportionality to  $\Delta$  in (3.57) is similar to a conventional Josephson tunnel junction. We conclude, that measuring stationary supercurrent is unlikely to reveal any topological physics in this system.

## Chapter 4

# Ionization

In this chapter the model presented before is modified by introducing a small oscillating external voltage. This perturbation allows the Majorana state to excite into continuum — the process we will call ionization. The main goal here is to find the ionization rate when the typical size of the photon is much smaller than the spectrum gap. Only regime with  $|g_L| \ll g_R$  is considered — this significantly simplifies the calculation, but still exhibits non-trivial physics with a number of different subregimes.

### 4.1 Introducing the perturbation

The perturbation is introduced as an oscillating voltage applied to the junction. This alters the Hamiltonian (2.3) in two ways — by the modification of the chemical potentials  $\mu_L, \mu_R$  and by making the superconducting phase difference  $\varphi = \phi_R - \phi_L$  time dependent. The second effect is governed by the Josephson relation:

$$U(\tau) = \frac{\hbar}{2e} \frac{\partial \varphi(\tau)}{\partial \tau} \quad (4.1)$$

The ionization voltage is assumed to be small compared to other energy parameters, and this smallness is present in both effects. However, if the frequency  $\omega$  of voltage is also small, the perturbation in  $\Delta$  induced by the second effect will have additional big multiplier  $\frac{\Delta}{\omega}$  and will dominate the perturbation in  $\mu$ . In this chapter only this regime is considered.

Time dependence of phase difference is introduced as:

$$\varphi(\tau) = \varphi_0 + \alpha \cos \omega \tau \quad (4.2)$$

where  $\varphi_0$  is an initial time independent phase difference and  $\alpha \ll 1$  is the amplitude of phase oscillations.

As was shown in section 3.3, there is a gauge transform  $U_\phi$ , which redistributes the phase difference between the wires, so the phase in a given wire can have any value. This ambiguity just reflects a fact, that only phase difference  $\varphi$  is an observable quantity, but not the phases  $\phi_L, \phi_R$

separately. However, when treating the time dependent phase difference this gauge transform also becomes time-dependent. After its application the additional term  $\dot{U}_{\phi(\tau)} U_{\phi(\tau)}^\dagger \propto \dot{\phi}(\tau)$  will appear, but, as  $\omega$  is small, it can be neglected. The corresponding condition on  $\omega$  will be established in section **ENTER SECTION**

As the term  $\dot{U}_{\phi(\tau)} U_{\phi(\tau)}^\dagger \propto \dot{\phi}(\tau)$  is negligible, we again can gauge all the phase difference into the boundary condition. Now the boundary condition is time-dependent. It's not very convenient, and to avoid dealing with it we reformulate the problem in terms of tunnel Hamiltonian, which allow us to treat both tunneling and time dependence simultaneously via perturbation theory.

## 4.2 Tunnel Hamiltonian approach

The main idea of this method is to hide all the time dependence and the tunnel effect in one single operator. To do so we need to rewrite the Hamiltonian as  $H = H_L + H_R + H_T$ , where  $H_{L,R}$  are the Hamiltonians of the left and right wire without any contact (corresponding to zero tunneling:  $t = 0$ ), and  $H_T$  is a tunnel Hamiltonian both containing the time dependence and mixing the wavefunctions from different wires. Here the following notation is used: the Hamiltonians  $H_L$ ,  $H_R$  and  $H_T$  are 8x8 matrices in combined Nambu-Gorkov and LR-space. In LR-space they have the following form:

$$H_L = \begin{pmatrix} h_L & 0 \\ 0 & 0 \end{pmatrix}_{LR} \quad H_R = \begin{pmatrix} 0 & 0 \\ 0 & h_R \end{pmatrix}_{LR} \quad H_T = \begin{pmatrix} 0 & h_T \\ h_T^\dagger & 0 \end{pmatrix}_{LR} \quad (4.3)$$

The Hamiltonians  $h_L$  and  $h_R$  eventually coincide with (2.2) with zero boundary condition. The Hamiltonian  $h_T$  is unknown – the goal is to make it in a way the corrections for the wavefunctions are restored. These wavefunctions and their first tunneling corrections are listed in appendix A.

The derivation of tunnel Hamiltonian matrix elements is presented in appendix B. Using the notation  $|\gamma_0\rangle$  for Majorana state and  $|\varepsilon, L_0\rangle, |\varepsilon, R_0\rangle$  for continuous spectra, we have the following:

$$H_T = \left( e^{i\frac{\varphi}{2}} + e^{-i\frac{\varphi}{2}} \right) \tilde{H}_T = \left( e^{i\frac{\varphi}{2}} + e^{-i\frac{\varphi}{2}} \right) \begin{pmatrix} 0 & \tilde{h}_T \\ \tilde{h}_T^\dagger & 0 \end{pmatrix} \quad (4.4)$$

$$\langle \gamma_0 | \tilde{h}_T^\dagger | E, L_0 \rangle = 4\sqrt{ug_R t} \zeta^2 f\left(\frac{E}{|g_L|}\right) \quad (4.5)$$

$$\langle \varepsilon, R_0 | \tilde{h}_T^\dagger | E, L_0 \rangle = -16u\zeta^2 t f\left(\frac{E}{|g_L|}\right) f\left(\frac{\varepsilon}{g_R}\right) \quad (4.6)$$

where  $f(x) = \sqrt{x^2 - 1} (x + \sqrt{x^2 - 1})$ . Note, that  $\tilde{h}_T = \tilde{h}_T^\dagger$ .

The fact, that all energy dependences here are described by a single function  $f(x)$  insinuates that maybe it's possible to make these calculations in a more beautiful way.

## 4.3 Ionization rate for $g_R \gg |g_L|$

### 4.3.1 Time dependence of perturbation

To obtain the ionization rate one should treat  $H_T$  as perturbation. For unperturbed system, described with  $H_0 = H_R + H_L$ , the electrons cannot get from wire to another, but  $H_T$  allows these processes, so the ionization can be described as a set of jumps from right to left wire (see fig. 4.1).

Figure 4.1: Ionization processes in terms of tunnel Hamiltonian

The approach to multiphoton ionization is described in appendix C. The rate is given by the formula (C.23). To use this formula, we decompose the perturbation in Fourier series. From (4.5) one finds, that  $V = H_T \propto \cos \frac{\varphi(\tau)}{2}$  with  $\varphi(\tau) = \varphi_0 + \alpha \cos \omega\tau$ . Using  $\alpha \ll 1$ , we write:

$$\begin{aligned}
 e^{\frac{i\varphi(\tau)}{2}} + e^{-\frac{i\varphi(\tau)}{2}} &\simeq e^{i\frac{\varphi_0}{2}} \sum_n \frac{(i\alpha)^n}{2^n n!} (e^{in\omega\tau} + e^{-in\omega\tau}) + c.c = \\
 &= \sum_n \frac{\alpha^n}{2^{2n-1} n!} (e^{in\omega\tau} + e^{-in\omega\tau}) \cos\left(\frac{\varphi_0}{2} + n\frac{\pi}{2}\right) \quad (4.7)
 \end{aligned}$$

so:

$$h_T = \sum_n h_{T,n} (e^{in\omega} + e^{-in\omega}) \quad h_{T,n} \approx \sum_n \frac{\alpha^n}{2^{2n-1} n!} \cos\left(\frac{\varphi_0}{2} + n\frac{\pi}{2}\right) \tilde{h}_T \quad (4.8)$$

Here the focus is on the case where the topological gap is much larger than the trivial one:  $|g_L| \ll g_R$ . In this case, the right continuum has high energies and does not participate in the ionization process. Indeed,

$$h_T G_\epsilon h_T = \frac{h_T |\gamma\rangle \langle \gamma| h_T}{\epsilon} + \int_{|E| > g_R} \frac{h_T |E, R_0\rangle \langle E, R_0| h_T}{\epsilon - E} \frac{dE}{N_R(E)} \quad (4.9)$$

So, when  $g_R \gg \epsilon \sim |g_L|$ , the second term is small and can be neglected. Then, the product  $\dots h_T G(E) h_T G(E) h_T \dots$  factorizes into individual factors of the form  $J_{nm} \equiv \langle \gamma | h_{T,n} G(E) h_{T,m} | \gamma \rangle$ .

### 4.3.2 Factorizing $w_{\mathcal{E}}$

As each entry in the sum within  $w_{\mathcal{E}}$  has the form  $\dots h_T G(E) h_T G(E) h_T \dots$ . For ionization rate we have:

$$\sqrt{\mathcal{I}} \propto \sum_N \sum_{\{n_i\}_M^N} \prod_{i=1}^N J_{n_i n_{i+1}} \quad (4.10)$$

Here  $N$  has the meaning of total number of absorbed photons,  $M$  is the closest to  $\frac{|g_L|}{\omega}$  integer, and the second sum is taken over all sets  $\{n_i\}_M^N$  of  $N$  items and  $\sum_i^N n_{i=1} = M$ .

The  $n, m$ -dependence factors out:

$$J_{nm} = \frac{\alpha^{n+m}}{2^{2(n+m)-2} n! m!} \cos\left(\frac{\varphi_0}{2} + n \frac{\pi}{2}\right) \cos\left(\frac{\varphi_0}{2} + m \frac{\pi}{2}\right) J_0(E) \quad (4.11)$$

$$J_0(E) = \langle \gamma | \tilde{h}_T G(E) \tilde{h}_T | \gamma \rangle \equiv \int_{cont.} \frac{|\langle \gamma | \tilde{h}_T | \epsilon \rangle|^2}{E - \epsilon} \frac{d\epsilon}{N_L(\epsilon)} \quad (4.12)$$

On each ionization step the particle can move to the state with energy  $E$  or  $-E$ , so:

$$J_0(E) = 2E \int_{|g_L|}^{\infty} \frac{|\langle \gamma | \tilde{h}_T | \epsilon \rangle|^2}{E^2 - \epsilon^2} \frac{d\epsilon}{N_L(\epsilon)} \quad (4.13)$$

recalling (4.5), we obtain:

$$J_0(E) = ET \frac{[-1 + \sqrt{1 - \lambda^2}]}{\lambda^2} \quad (4.14)$$

where  $\lambda = \frac{E}{|g_L|}$ ,  $T = \frac{g_R (\zeta^2 t)^2}{|g_L|}$ . We consider  $T \ll 1$ , so the systems remains in a strong tunneling limit.

Thus, the elementary block in our product for small enough  $n$  becomes:

$$\frac{J_{nm}}{E + n\omega} \approx \frac{J_{nm}}{E} = \left(\frac{\alpha}{4}\right)^{n+m} B_n B_m^* T^{\frac{-1 + \sqrt{1 - \lambda^2}}{\lambda^2}} \quad (4.15)$$

where

$$B_n = \frac{2}{n!} \cos\left(\frac{\phi_0}{2} + \frac{\pi n}{2}\right) \quad (4.16)$$

The prefactor  $(\alpha/4)^{n+m}$  yields  $(\alpha/4)^{\mathcal{E}/\omega}$  for any trajectory and therefore do not affect summation and optimization. Thus one has  $B_n B_m T^{\frac{-1 + \sqrt{1 - \lambda^2}}{\lambda^2}}$  to optimize.

Now consider a slice of the ionization process, i.e. a part of the full ionization product, which runs from energy  $E$  to  $E + \Delta E$  where  $\Delta E = M\omega$  with a large  $M$ . One can assume that within that process, a large number  $2N$  of photons is absorbed, but energy does not change significantly,  $\Delta E \ll E$ , so that  $\lambda$  can be considered a constant within that process. Denoting:

$$T_\lambda = -4T \frac{[-1 + \sqrt{1 - \lambda^2}]}{\lambda^2} \quad (4.17)$$

Then, one finds, that the ionization rate is  $\mathcal{I} \propto \mathcal{J}^2$  where:

$$\mathcal{J}(\lambda) \equiv \sum_N \sum_{\{n\}_N^M} \prod_{i=1}^N \frac{J_{n_i n_{i+1}}}{E} = \left(\frac{\alpha}{4}\right)^M \sum_N (-T_\lambda)^{\frac{N}{2}} \mathcal{J}_N(\lambda) \quad (4.18)$$

$$\mathcal{J}_N(\lambda) = \sum_{\{n\}_{2N}^M} \prod_{i=1}^N \frac{\cos\left(\frac{\phi_0}{2} + \frac{\pi n_{2i}}{2}\right)}{n_i!} \quad (4.19)$$

So to obtain the ionization rate up to a preexponential constant, one should compute  $\mathcal{J}(\lambda)$  and take the product  $\prod_{\lambda_k} \mathcal{J}(\lambda_k)$  where  $\lambda_k$  corresponds for the  $k$ -th slice of the ionization process.

### 4.3.3 Estimation for optimal photon number

We begin dealing with (4.18) by finding the optimal photon number  $N_*$ . This number corresponds to the largest term in the sum (4.18).

The first step is to use Poisson summation formula:

$$\sum_{n=-\infty}^{\infty} \delta(x - n) = \sum_{k=-\infty}^{\infty} e^{2i\pi k x} \quad (4.20)$$

so:

$$\begin{aligned} \mathcal{J}_N(\lambda) &= \\ &= \left( \sum_{k_1=-\infty}^{\infty} \cdots \sum_{k_{2N-1}=-\infty}^{\infty} \right) \prod_{i=1}^{2N-1} \left( \int dx_i e^{2i\pi k_i x_i} \frac{\cos\left(\frac{\varphi_0}{2} + \frac{\pi x_i}{2}\right)}{\Gamma(x_i + 1)} \right) \frac{\cos\left(\frac{\varphi_0}{2} + \frac{\pi x_{2N}}{2}\right)}{\Gamma(x_{2N} + 1)} \end{aligned} \quad (4.21)$$

where  $x_{2N} \equiv M - \sum_{i=1}^{2N-1} x_i$ . This can be rewritten as:

$$\mathcal{J}_N(\lambda) = \frac{1}{2^{2N}} \sum_{\mathbf{k}} \left( \sum_{s_1=\pm 1} \cdots \sum_{s_{2N}=\pm 1} \right) \left( \prod_{i=1}^{2N-1} \int dx_i \right) e^{S[\mathbf{x}]} \quad (4.22)$$

with

$$S[\mathbf{x}] = - \sum_{i=1}^{2N} \log \Gamma(x_i + 1) + 2i\pi \sum_{i=1}^{2N-1} k_i x_i + i \sum_{i=1}^{2N} s_i \left( \frac{\varphi_0}{2} + \frac{\pi x_i}{2} \right) \quad (4.23)$$

As  $N$  and  $M$  are large, we assume that  $x_i$  at saddle points are also large, so the Stirling approximation is relevant:  $\log \Gamma(x) \approx x \log x - x$ . This allows us to neglect all the terms in (4.23) except for the first one and get (recall, that  $x_{2N} = M - \sum_{i=1}^{2N-1} x_i$ ):

$$\frac{\partial}{\partial x_i} S[\mathbf{x}] \approx \log x_{2N} - \log x_i \quad (4.24)$$

So, at the saddle point all  $x_i$  are equal to  $\frac{M}{2N}$ .

Each  $x_i$  corresponds to its own  $n_i$ . In saddle point approximation we can take only terms with  $n_i = x_i^{\text{saddle}}$  in sum (4.19). Then the sum (4.18) becomes:

$$\mathcal{J}(\lambda) \approx \sum_N A_N (-T_\lambda)^{\frac{N}{2}} e^{-M \log \frac{M}{2N}} = \sum_N A_N (-1)^{\frac{N}{2}} e^{\frac{N}{2} \log T_\lambda - M \log \frac{M}{2N}} \quad (4.25)$$

where everything not important for the estimation is put in the multipliers  $A_N$ .

It's easy to see, that the biggest term in (4.23) corresponds to the  $N_* = 2M \log \frac{1}{T_\lambda}$ . This is the optimal photon number for the slice for energy range from  $E$  to  $E + \Delta E$  with  $E = |g_L| \lambda$  and  $\Delta E = \omega M$ . Consequentially the optimal photon size is given by  $n_* = \frac{M}{2N_*} = \log \frac{1}{T_\lambda}$ .

#### 4.3.4 Using multinomial formula

To treat (4.19) more accurately it's convenient to use the multinomial formula:

$$\frac{d^n}{dx^n} \prod_i f_i(x) = \sum_{\sum_i k_i = n} \binom{n}{k_1, k_2, \dots, k_n} \prod_i \frac{d^{k_i}}{dx^{k_i}} f_i \quad (4.26)$$

For the cosine product it can be applied in a following way:

$$\sum_{\{n\}_N^M} \prod_{i=1}^N \frac{\cos(\chi + \frac{\pi n_i}{2})}{n_i!} = \sum_{\{n\}_N^M} \prod_{i=1}^N \frac{D_\chi^{n_i}}{n_i!} \cos \chi = \frac{1}{M!} D_\chi^M \cos^N \chi \quad (4.27)$$

where  $\chi = \frac{\varphi_0}{2}$ . Then some algebra should be used:

$$\frac{1}{M!} D_\chi^M \cos^N \chi = \frac{1}{2^N M!} D_\chi^M \sum_{k=0}^N C_k^N e^{i\chi(N-2k)} = \frac{e^{i\chi N + iM\pi/2}}{2^N M!} \sum_{k=0}^N C_k^N (N-2k)^M e^{-2ki\chi} \quad (4.28)$$

So:

$$\mathcal{J}_N(\lambda) = \frac{e^{i\frac{\phi_0}{2}N + iM\pi/2}}{2^N M!} \sum_{k=0}^N C_k^N (N-2k)^M e^{-2ki\chi} \quad (4.29)$$

Now, in the sum, the ratio of consecutive summands is  $\frac{a_{k+1}}{a_k} = \frac{C_{k+1}^N}{C_k^N} \left(\frac{N-2k-2}{N-2k}\right)^M$ . For  $k < N/2$  both factors here are decreasing, so the largest ratio is  $\frac{a_1}{a_0} = N \left(\frac{N-2}{N}\right)^M \simeq N e^{-2M/N}$ . The most important terms in this sum define in which regime the system is and what the ionization rate would be.

The expression (4.19) can be rewritten with the help of the Poisson summation formula:

$$\mathcal{J} = \left(\frac{\alpha}{4}\right)^M \sum_N \mathcal{J}_N \quad (4.30)$$

One can anticipate that the typical (i.e. most important) value of  $N$  is given by  $N_* = \frac{2M}{n_*}$  with  $n_* = \log \frac{1}{T_\lambda}$ . It can be shown from considering the action  $s = \log \frac{1}{T_\lambda} - \frac{2}{2M}$  which appears in this sum. Taking  $N = N_*$  one can rewrite the condition  $\left|\frac{a_1}{a_0}\right| \ll 1$  as  $\frac{2M}{n_*} \ll e^{n_*}$ . This condition separates two regimes of the system — pure Andreev regime, when only the first and the last terms in the sum are relevant, and the Andreev+Normal regime, when other terms should be taken into account.

### 4.3.5 Pure Andreev regime

When  $\frac{2M}{n_*} \ll e^{n_*}$  the sum (4.28) can be rewritten as:

$$\mathcal{J} \approx \left(\frac{\alpha}{4}\right)^M \sum_N (-T_\lambda)^{N/2} \frac{N^M}{M! 2^N} \times 2 \cos \left( \chi N + \frac{M\pi}{2} \right) \quad (4.31)$$

The preexponent is not the object of interest, while the fixed parity of  $N$  should be taken into account (it is fixed since the continuum state is available only on the left side of the junction).

Replace  $N = 2K$  and obtain:

$$\begin{aligned}
I_M &= \left(\frac{\alpha}{4}\right)^M \sum_{K=1}^{\infty} (-T_\lambda)^K \frac{(2K)^M}{M! 2^{2K}} \times 2 \cos\left(\phi_0 K + \frac{M\pi}{2}\right) = \\
&= \frac{2}{M!} \left(\frac{\alpha}{4}\right)^M \Re \left[ i^M \sum_K (-T_\lambda)^K \frac{(2K)^M}{2^{2K}} e^{i\phi_0 K} \right] = \\
&= \frac{2^{M+1}}{M!} \left(\frac{\alpha}{4}\right)^M \Re \left[ i^M \text{Li}_{-M} \left( \frac{T_\lambda}{4} e^{i(\phi_0 + \pi)} \right) \right] \quad (4.32)
\end{aligned}$$

The polylogarithmic function can be rewritten in the following useful way

$$\text{Li}_s(e^\mu) = \Gamma(1-s) \sum_{r \in \mathbb{Z}} (2r\pi i - \mu)^{s-1}$$

Substituting, we get

$$\text{Li}_{-M} \left( \frac{T_\lambda}{4} e^{i(\phi_0 + \pi)} \right) = \Gamma(1+M) \sum_{r \in \mathbb{Z}} \left( i[2r\pi - \pi - \phi_0] + \ln \frac{4}{T_\lambda} \right)^{-M-1}$$

Denoting  $\ln \frac{4}{T_\lambda} = n_\lambda$  we have the ratio of consecutive terms in the sum (assuming they are not too far from the largest term):

$$\left| \frac{a_{r+1}}{a_r} \right| \sim \left( \frac{n_\lambda^2 + (\gamma_r + 2\pi)^2}{n_\lambda^2 + \gamma_r^2} \right)^{-1-M} \sim \left( 1 + \frac{2\pi(2\pi + 2\gamma_r)}{n_\lambda^2 + \gamma_r^2} \right)^{-M} \sim \exp \left[ \frac{4\pi M(\pi + \gamma_r)}{n_\lambda^2} \right]$$

where  $\gamma_r = i(2r\pi - \pi - \phi_0)$ . There are two values of  $r$  for which  $|\pi + \gamma_r|$  is smallest, for the rest it is not smaller than  $2\pi$  so that the rest of the terms are smaller by at least

$$\exp \left[ -\frac{8\pi^2 M}{n_\lambda^2} \right]$$

**Subcase**

$$\exp \left[ \frac{8\pi^2 M}{n_\lambda^2} \right] \gg 1$$

in which case the sum over  $r$  is dominated by the two largest terms (typically by just one term except for the case when  $\phi_0$  is close to zero). We dictate  $-\pi < \phi_0 < \pi$  so that the two dominating terms correspond to  $r = 0, 1$ . We have in that limit

$$\text{Li}_{-M} \left( \frac{T_\lambda}{4} e^{i(\phi_0 + \pi)} \right) \simeq M! \left( \frac{1}{(n_\lambda + i(\pi - \phi_0))^{M+1}} + \frac{1}{(n_\lambda + i(-\pi - \phi_0))^{M+1}} \right)$$

and thus

$$I_M = 2 \left( \frac{\alpha}{2} \right)^M \Re \left[ i^M \left( \frac{1}{(n_\lambda + i(\pi - \phi_0))^{M+1}} + \frac{1}{(n_\lambda + i(-\pi - \phi_0))^{M+1}} \right) \right]$$

We have

$$[n_\lambda + i(\pi - \phi_0)]^{M+1} = [n_\lambda^2 + (\pi - \phi_0)^2]^{\frac{M+1}{2}} e^{i(M+1) \arctan \frac{\pi - \phi_0}{n_\lambda}}$$

and

$$\begin{aligned} I_M &= 2 \left( \frac{\alpha}{2} \right)^M \Re \left[ \frac{e^{\frac{iM\pi}{2} - i(M+1) \arctan \frac{\pi - \phi_0}{n_\lambda}}}{[n_\lambda^2 + (\pi - \phi_0)^2]^{\frac{M+1}{2}}} + \frac{e^{\frac{iM\pi}{2} + i(M+1) \arctan \frac{\pi + \phi_0}{n_\lambda}}}{[n_\lambda^2 + (\pi + \phi_0)^2]^{\frac{M+1}{2}}} \right] = \\ &= 2 \left( \frac{\alpha}{2} \right)^M \left[ \frac{\cos \left( \frac{M\pi}{2} - (M+1) \arctan \frac{\pi - \phi_0}{n_\lambda} \right)}{[n_\lambda^2 + (\pi - \phi_0)^2]^{\frac{M+1}{2}}} + \frac{\cos \left( \frac{M\pi}{2} + (M+1) \arctan \frac{\pi + \phi_0}{n_\lambda} \right)}{[n_\lambda^2 + (\pi + \phi_0)^2]^{\frac{M+1}{2}}} \right] \end{aligned}$$

This contains some complicated oscillations but within exponential accuracy we may write

$$I_M \sim \exp M \left[ \ln \frac{\alpha}{2} - \frac{1}{2} \ln(n_\lambda^2 + (\pi - |\varphi_0|)^2) \right]$$

This is almost the final formula for the ionization amplitude. To finalize it, we have to replace the action at fixed  $n_\lambda$  by an integration over  $\lambda$  to account for the slowly changing energy of the quasiparticle. However, it is unclear, what is required of  $M, n_*$  to allow such a procedure. The procedure assumes that we can roughly write  $I_M = \prod_j I_{M_j}(\lambda_j)$  where the full process is split into layers counted by  $j$  where within each layer energy is roughly the same and  $\sum M_j = M$ , but  $M_j$  is relatively large (so that  $N_j$  remains large). Hypothetically, if our principal conditions are met (the ones that limit the sum to highest harmonics and allow the use of asymptotics for Li) then we can split  $M$  into layers which individually obey the same limits. Therefore, in the mathematical limit the procedure seems correct, but it is hard to tell, what accuracy it has. We have

$$\begin{aligned} s_\lambda &= \int_0^1 \ln(n_\lambda^2 + (\pi - |\varphi_0|)^2) d\lambda = \int_0^1 \ln \left( \ln \left( \frac{4}{T_\lambda} \right)^2 + (\pi - |\varphi_0|)^2 \right) d\lambda \\ &= \int_0^1 \ln \left( \left[ \ln \frac{\lambda^2}{T_0(1 - \sqrt{1 - \lambda^2})} \right]^2 + (\pi - |\varphi_0|)^2 \right) d\lambda \end{aligned}$$

Calculation of the  $\lambda$ -integral:

$$\int_0^1 \ln(n_\lambda^2 + (\pi - |\varphi_0|)^2) d\lambda = \int_0^1 \left( 2 \ln n_\lambda + \frac{(\pi - |\varphi_0|)^2}{n_\lambda^2} \right) d\lambda$$

Separately we find:

$$\int_0^1 \ln n_\lambda d\lambda = \ln \frac{1}{T} + \int_0^1 \ln \frac{\lambda^2}{1 - \sqrt{1 - \lambda^2}} d\lambda = \ln \frac{1}{T} + \frac{\pi}{2} - 1.$$

For the second integral we have

$$\int_0^1 \frac{1}{n_\lambda^2} d\lambda = \int_0^1 \frac{1}{\left[ \ln \frac{1}{T} + \ln \frac{\lambda^2}{1 - \sqrt{1 - \lambda^2}} \right]^2} d\lambda = \frac{1}{(\ln \frac{1}{T})^2} + O\left(\frac{1}{(\ln \frac{1}{T})^3}\right)$$

Thus, we get

$$s_\lambda = 2 \ln \frac{1}{T} + \pi - 2 + \frac{(\pi - |\varphi_0|)^2}{(\ln \frac{1}{T})^2} + O\left(\frac{1}{(\ln \frac{1}{T})^3}\right)$$

and the final result in this limit (only pure MAR (multiple Andreev reflections)) is:

$$P = \exp \left[ -\frac{g_L}{\omega} \left( 2 \ln \frac{2}{\alpha} + 2 \ln \ln \frac{1}{T} + \pi - 2 + \frac{(\pi - |\varphi_0|)^2}{(\ln \frac{1}{T})^2} + O\left(\frac{1}{(\ln \frac{1}{T})^3}\right) \right) \right]$$

$$(\ln \frac{1}{T})^2 \ll \frac{g_L}{\omega} \ll (\ln \frac{1}{T})^2 e^{1/T}$$

and in the second regime,

$$P = \exp \left[ -\frac{g_L}{\omega} \left( 2 \ln \frac{2}{\alpha} + 2 \ln \ln \frac{1}{T} + \pi - 2 + o(1) \right) \right]$$

$$(\ln \frac{1}{T})^2 \ll \frac{g_L}{\omega}$$

This includes the previous answer. The  $o(1)$  is to be determined.

Finally, in the case where  $n_* \ll M \ll n_*^2$  I do Poisson to calculate  $\text{Li}$  and find that it behaves strangely: I get  $e^{-M \ln n_\lambda - \frac{1}{2} \frac{M^2}{n_\lambda} n_\lambda^2 / M + \text{corr.}}$  where  $M/n_\lambda$  denotes the fractional part of the number (from  $-1/2$  to  $1/2$ ). The number within changes quickly with  $\lambda$  and therefore  $^2 \rightarrow \langle^2 \rangle = 1/12$ . Then, we get

$$P = \exp \left[ -\frac{g_L}{\omega} \left( 2 \ln \frac{2}{\alpha} + 2 \ln \ln \frac{1}{T} + \pi - 2 \right) + \frac{1}{12} \frac{(\ln \frac{1}{T})^2}{g_L/\omega} + o\left(\frac{(\ln \frac{1}{T})^2}{g_L/\omega}\right) \right] \quad (4.33)$$

$$(\ln \frac{1}{T}) \ll \frac{g_L}{\omega} < (\ln \frac{1}{T})^2 \quad (4.34)$$

### Pure Andreev regime regime: intermediate case: fixed photon number

Above we considered  $M \gg n_*$  which lead to a simple asymptotic of the function  $\text{Li}_{-M}(e^{-n_*+i(\phi_0+\pi)})$ . There is also the intermediate case where  $n_* \ll M \ll n_*^2$ . In this case the dominating term(s) have large index  $K$ , but the gaussian envelope is very narrow, with a width  $\ll 1$  which means that the full series is dominated by a single term (this is in full agreement with the fact that the second form of  $\text{Li}$  is now wide, i.e. converges over a large number of  $r$ -terms). It is easy to show that the optimal term has the integer index  $K_0$  closest to the real saddle-point  $K_* = M/n_*$ . We write

$$K_* = K_0 + \xi, \quad \text{with} \quad \xi \in (-\frac{1}{2}, \frac{1}{2})$$

Then, omitting the complex phase, we write

$$\begin{aligned} \text{Li}_{-M}(e^{-n_*+i(\phi_0+\pi)}) &\approx a_{K_0} \propto e^{-n_*(K_*-\xi)+M \ln(K_0-\xi)} = \\ &= e^{-M+n_*\xi+M \ln \frac{M}{n_*}+M \ln(1-\frac{\xi n_*}{M})} = e^{-M+M \ln \frac{M}{n_*}-\frac{\xi^2 n_*^2}{2M}+O\left(\frac{n_*^3}{M^2}\right)} \end{aligned}$$

Substituting this result for the  $\text{Li}$  function we obtain in this regime (to exponential accuracy)

$$I \sim \frac{1}{M!} \left(\frac{\alpha}{2}\right)^M e^{-M+M \ln \frac{M}{n_*}-\frac{\xi^2 n_*^2}{2M}+O\left(\frac{n_*^3}{M^2}\right)} = e^{-M \ln \frac{2}{\alpha}-M \ln n_*-\frac{\xi^2 n_*^2}{2M}+O\left(\frac{\xi^3 n_*^3}{M^2}\right)}$$

and for the probability we write:

$$P_2 = \exp \left[ -M \left( 2 \ln \frac{2}{\alpha} + 2 \ln n_* \right) - \left\{ \frac{M}{n_*} \right\}^2 \frac{n_*^2}{M} + O \left( \frac{n_*^3}{M^2} \right) \right], \quad n_* \ll M \ll n_*^2$$

### 4.3.6 Andreev+Normal regime

For completeness, let us also consider the case  $M/N \ll \log N$ . In this case the sum over  $k$  is not defined by the two edge terms. We write:

$$\sum_{k=0}^N C_k^N (N-2k)^M e^{-2ki\chi} = \sum_{k=0}^N e^{-S_0(k)-2ki\chi}$$

where the action  $S_0$  is

$$\begin{aligned} S_0 &= -\ln C_k^N - M \ln(N-2k) = -N \ln N + k \ln k + (N-k) \ln(N-k) - \\ &\quad - M \ln(N-2k) - \frac{1}{2} \ln \frac{N}{2\pi(N-k)k} + \dots \end{aligned}$$

The stationary point of that action obeys  $\partial S_0/\partial k = 0$ :

$$\ln k - \ln(N - k) + \frac{2M}{N - 2k} + \frac{1}{2k} - \frac{1}{2(N - k)} = 0$$

As expected,  $k \rightarrow N - k$  changes the sign of this. We seek for the stationary point with  $k < N/2$ . We have the transcendent equation (terms  $\sim 1/k, 1/N$  are neglected)

$$\ln\left(\frac{N}{k} - 1\right) = \frac{2M/N}{1 - 2k/N}$$

This is generally unsolvable, but if we assume that  $M/N \gg 1$  then we get  $k/N \ll 1$  and the asymptotics is

$$-\ln \frac{k}{N} = 2 \frac{M}{N}$$

$$k_0 = N e^{-2M/N}$$

We remind that this happens in the regimes  $1 \ll M/N \ll \ln N$ . At the same time, to have  $k \gg 1$  produces the additional constraint  $M/N \ll \frac{1}{2} \ln N$ . At this saddle point,  $k = k_0$ , we have

$$\frac{\partial^2 S_0}{\partial k^2} \approx \frac{1}{k} + \frac{1}{N - k} + \frac{4M}{(N - 2k)^2} \approx \frac{1}{k_0} + \frac{4M}{N^2} = \frac{1}{N} \left( e^{2M/N} + \frac{4M}{N} \right) \approx \frac{1}{k_0}$$

where we made use of  $M/N \gg 1$ . The action itself if

$$\begin{aligned} S_0 &= -N \ln N + k_0 \ln k_0 + (N - k_0) \ln(N - k_0) - M \ln(N - 2k_0) - \frac{1}{2} \ln \frac{N}{2\pi(N - k_0)k_0} \\ &\approx -N \ln N + k_0 \ln k_0 + (N - k_0) \left[ \ln N + \ln\left(1 - \frac{k_0}{N}\right) \right] - \\ &\quad - M \left[ \ln N + \ln\left(1 - \frac{2k_0}{N}\right) \right] - \frac{1}{2} \ln \frac{1}{2\pi k_0} + \frac{1}{2} \ln\left(1 - \frac{k_0}{N}\right) \end{aligned}$$

If we are interested in the exponent and preexponent, we can only omit terms of the order  $o(1)$  in  $S_0$ , for example the very last term in the above. We get

$$S_0 \approx -(M + k_0) \ln N + \left(k_0 + \frac{1}{2}\right) \ln k_0 + (N - k_0) \ln\left(1 - \frac{k_0}{N}\right) - M \ln\left(1 - \frac{2k_0}{N}\right) - \frac{1}{2} \ln \frac{1}{2\pi}$$

However, since our solution for  $k_0$  is itself approximate, we should restrict ourselves to

exponential accuracy here and keep only major terms, linear in  $M$

$$\begin{aligned} S_0 &= -M \ln N + O(k_0 \frac{M}{N}, k_0 \ln N, k_0, k_0 \ln k_0) \\ &= -M \ln N + O(k_0 \ln N) \end{aligned}$$

We now integrate using the Poisson formula:

$$\begin{aligned} \sum_{k=0}^{N/2} e^{-S_0(k)-2ki\chi} &= \sum_{p \in \mathbb{Z}} e^{-S_0(k_0)-2k_0i(\chi-\pi p)} \int dk e^{-\frac{1}{2k_0}(k-k_0)^2-2(k-k_0)i(\chi-\pi p)} \\ &= \sum_{p \in \mathbb{Z}} e^{-S_0(k_0)-2k_0i(\chi-\pi p)-2(\chi-\pi p)^2 k_0} \sqrt{2\pi k_0} \end{aligned}$$

Assuming  $\phi_0$  is not close to  $\pm\pi$  the above is dominated by the term with  $p = 0$  because  $k_0 \gg$

1. If we are close to  $\pi$  phase difference, there are two main terms, but, to an exponential accuracy the answer is still the same (the only problem that could possibly arise is alternating-sign sums that might appear later when summing over  $N$  and give incorrect results due to the approximation we do now. Maybe this can be mended easily by restoring these terms via replicating the result via  $\phi_0 \rightarrow \phi_0 + 2\pi p$ ). In the above, we only integrated near the saddle-point with  $k_0 < N/2$ , there remains the symmetric saddle at  $N - k_0$ . This adds the complex conjugate to the result (but first we must restore some prefactors):

$$\begin{aligned} \frac{i^M e^{i\chi N}}{M! 2^N} \sum_{k=0}^N C_k^N (N-2k)^M e^{-2ki\chi} &= \\ \sqrt{2\pi k_0} \frac{e^{i\chi N + iM\pi/2}}{M! 2^N} \sum_{p \in \mathbb{Z}} e^{-S_0(k_0)-2k_0i(\chi-\pi p)-2(\chi-\pi p)^2 k_0} + c.c. &= \\ = 2 \frac{\sqrt{2\pi k_0}}{M! 2^N} e^{-S_0} \sum_{p \in \mathbb{Z}} \exp[-2(\chi-\pi p)^2 k_0] \cos \left[ -2k_0(\chi-\pi p) + \chi N + \frac{M\pi}{2} \right] \end{aligned}$$

The sum can be written in terms of the elliptic theta-function. But thus is not particularly helpful. Instead, we risk omitting all terms except the  $p = 0$  -terms. This preserves exponential accuracy, but risks errors in further summation over  $N$ , since that summation may be an alternating sign sum susceptible to minor corrections to the terms. We get

$$2 \frac{\sqrt{2\pi k_0}}{M! 2^N} e^{-S_0} \sum_{p \in \mathbb{Z}} \exp[-\chi^2 k_0] \cos \left[ \chi(N-2k_0) + \frac{M\pi}{2} \right]$$

The next step is to sum this over  $N$ . Remember that  $k_0 = N e^{-2M/N}$  and  $S_0 = S_0(M, N, k_0(M, N))$ .

We now have

$$\Re \frac{i^M}{M!} \left(\frac{\alpha}{4}\right)^M \sum_N \left(-\frac{T_\lambda}{4}\right)^{N/2} \sqrt{k_0} e^{-S_0 - \chi^2 k_0 + i\chi(N-2k_0)}$$

where we omitted a few pre-exponential factors. We now replace  $N = 2K$  and rewrite:

$$\frac{1}{M!} \left(\frac{\alpha}{4}\right)^M \Re i^M \sum_N \left(-\frac{T_\lambda}{4}\right)^K \sqrt{k_0} e^{-S_0 - \frac{\phi_0^2 k_0}{4} + i\phi_0(K-k_0)}, \quad k_0 = \frac{K}{2} e^{-M/K}$$

We now again have to use the saddle approximation when summing over  $K$ . The total action, as a function of  $K$  is

$$S(K) = S_0 + \frac{\phi_0^2 k_0}{4} - i\phi_0(K - k_0) - K \left( \frac{i\pi}{2} + \ln \frac{T_\lambda}{4} \right).$$

We are again looking for the stationary point. At this point we calculate  $\partial S / \partial K$  to the main order. In particular, since we expect  $M \gg K$  we may neglect the  $k_0$ -terms that are seen explicitly: we have

$$\begin{aligned} \frac{\partial S}{\partial K} &\simeq \frac{\partial S_0}{\partial K} + i \left( \phi_0 + \frac{\pi}{2} + \ln \frac{T_\lambda}{4} \right) \\ &\simeq -\frac{M}{K} - \left( i\phi_0 + i\frac{\pi}{2} + \ln \frac{T_\lambda}{4} \right) \end{aligned}$$

which immediately gives  $K = M/n_\lambda$  where  $n_\lambda = \ln(4/T_\lambda)$ . This is the same size as before, which is a good sign! Thus, we mainly have to calculate

The projected answer is:

$$\begin{aligned} I &= e^{-Ms} \\ s &= \ln \frac{2}{\alpha} + \int_0^1 \ln n_\lambda d\lambda + o(1) \end{aligned}$$

**Single-photon case.** Here we simply have one photon with  $N = M$  which produces the  $(\alpha/4)^M / M!$  factor and therefore, to exponential accuracy we get

$$P \sim T \exp \left[ -M \left( 2 \ln \frac{4}{\alpha} - \ln M + 1 \right) \right]$$

## 4.4 Results

Here we collect results for the ionization rate (i.e. probability  $P \propto I_M^2$ ) within exponential accuracy. There are for parametric regimes (for now we forget about the adiabaticity condition – we will later discuss it). We have the notations  $M = g_L/\omega$  is the total number of energy quanta needed to ionize. We have  $n_* = \ln \frac{1}{T}$  – **twice** the optimal size of a photon (in quanta of  $\omega$ ). The amount of photons in a configuration is called  $N$ , its optimum amount is  $N_* = 2M/n_*$ . The results are as follows:

### Ionization rate

1. Single-photon case:  $M < n_*$ . In this case, the tunneling parameter  $T$  is so small that it is best to use a single photon to minimize the  $T^{N/2}$  factor in the amplitude  $I_{NM}$ . Then we have

$$P_1 \sim T \exp \left[ -M \left( 2 \ln \frac{4}{\alpha} - 2 \ln M + 2 \right) \right] \quad (4.35)$$

2. Fixed number of photons case:  $n_* \ll M \ll n_*^2$ . In this case it is optimal to use multiple photons, more sepcifically exactly  $N_*$  photons (rounded to the nearest integer, of course). Processes with different  $N$  do not contribute (their contribution is negligible). We get

$$P_{N_*} \sim \exp \left[ -M \left( 2 \ln \frac{2}{\alpha} + 2 \ln n_* + \pi - 2 + \left\{ \frac{M}{n_*} \right\}^2 \frac{n_*^2}{M^2} + O \left( \frac{n_*^3}{M^3} \right) \right) \right] \quad (4.36)$$

Here  $\{M/n_*\} \in (-0.5, 0.5)$  stand for the fractional part of the argument (or rather distance to nearest integer). We see that integer effects are important in this regime.

3. Fluctuating photon number case:  $n_*^2 \ll M$ . Now, for combinatorial reasons, contributions from  $N \neq N_*$  become important, and we get

$$P_{N_*+\delta N} \sim \exp \left[ -M \left( 2 \ln \frac{2}{\alpha} + 2 \ln n_* + \pi - 2 + o(1) \right) \right] \quad (4.37)$$

In this case  $N$  fluctuates significantly ( $\delta N = N - N_*$  is typically much larger than unity but much smaller than  $N_*$ . It can be found if needed). Thus, no integer effects remain.

4. Sub-case of (3) where only Andreev reflection happens:  $n_*^2 \ll M \ll n_* e^{n_*}$ . In this case we take only left term in each cosine, or only right – this produces the largest contribution to ionization. [At higher  $M$  some normal reflections start to happen (combinatorically they

become important. Or, in other words, their phase space becomes large – there are many such “trajectories”). This case is very technically involved]. So, if only MAR (multiple Andreev reflection) happens, then we can further refine the expression for the ionization rate and get

$$P_{N_*+\delta N}^{(MAR)} \sim \exp \left[ -M \left( 2 \ln \frac{2}{\alpha} + 2 \ln n_* + \pi - 2 + \frac{(\pi - |\varphi_0|)^2}{n_*^2} + O \left( \frac{1}{n_*^3} \right) \right) \right] \quad (4.38)$$

**Note on all cases and energy dependence:** the Green’s function energy depends on the current energy (i.e. sum of energies of all previously absorbed photons). Therefore,  $T$  becomes a function of  $\lambda = E/g_L$ . Note that this dependence is slow –  $T$  is rescaled by the very nice function  $c(\lambda) = (1 - \sqrt{1 - \lambda^2})/\lambda^2 \in (1/2, 1)$ . So that  $n_*$  only changes by  $-\ln c(0) = \ln 2 \simeq 0.3$ . This energy dependence is actually accounted for and is the origin of the  $\pi - 2$  terms in expressions for  $P$ .

## Chapter 5

# Discussion

In this chapter the obtained results are summarized and the potential experimental realization of the system is discussed.

### 5.0.1 Results summary

The results, obtained in chapters 3 and 4 has different potential for experiment realization. The subgap spectra can be obtained through the conductance measurements like was done in [22] and [24]. However as the conductance peak can be weakened by thermal broadening and scattering on the impurities, so it can be difficult to test that there are no states except for Majoranas – especially for the states near the gap. The results of chapter 3 tell, that measuring the system's supercurrent wouldn't be much different from the short Josephson junction problem.

However the ionization rates from the chapter 4 has a potential for being used in experiment. Indeed, if the system has no Majorana state, the ionization rate will at least get a factor of 2 in the exponent, as when there is no Majorana near the barrier, to ionized the the system needs to break a cooper pair from the condensate, thus it needs to overcome the gap twice.

### 5.0.2 Possible experimental realization

The system, described in chapter 2, can be potentially be built in experimental setup similar to the ones used in [22] and [24].

The first problem, that seemingly makes all the work useless, is the fact that 1D superconductors don't exists due to the presence of fluctuations. However there is a bypass — one can make superconducting wires artificially, taking a metallic or semiconducting wire and proximiting it to a strong superconductor. This is a well known method, used, for example, in [22] and [24].

The proposed setup, for the system is presented on 5.1. A metallic or semiconducting wire (yellow) is being put on a insulator (gray) and proximitized to couple of superconductors (violet and cyan). It's important to make the superconductors separate, to obtain a phase difference and avoid shortcutting the barrier. The barrier itself can be created using a gate (red) with a big negative voltage on it. The chemical potentials in the wires can be adjusted in a similar way, by using a gates near each wire (green).

Figure 5.1: Possible experimental realization of the system

The procedure of adjusting the parameters of the model from the chapter 2 can be the following: at first the system is created, with superconductivity inside the wires being as similar, as possible. This may require a really advanced technique of fabricating the samples. After that the magnetic field  $B$  turns and adjusts to be a little bigger than  $\Delta$ . After that the gates should be set to switch the wires to desired topology and create a tunnel barrier.

When the model was chosen it was considered that it's much easier to make spatially inhomogeneous electric than magnetic field. It's also important, that the spin-orbit coupling energy inside the wire should be much stronger than the the superconducting gap. However, this condition can be satisfied as the proximitized superconductivity can be weakened by a proper fabrication process.

## Chapter 6

# Conclusion

In this work the system of two superconducting wires connected with a tunnel junction is considered. The spectrum is obtained, the supercurrent and the ionization rate for  $g_R \gg |g_L|$  is calculated. Despite the fact, that the ionization in this limit is factorized, it possesses its own rich physics with four different regimes of ionization.

Authors hope, that the results of this work can be used for improving the techniques of detecting Majorana fermions in superconducting wires

## Appendix A

# Wavefunctions for the stationary contact

Here the eigenstates of the junction are presented in leading and subleading order on the tunneling constant  $t$ . Only long-wave ( $\psi_{\text{medium}}$  and  $\psi_{\text{longest}}$ ) part is presented here, as it's sufficient for chapter 4.

The states in Nambu-Gorkov space are written in bra-ket notation. For zero tunneling they are:  $|\gamma_0\rangle$ — the Majorana state and  $|\varepsilon, L_0\rangle, |\varepsilon, R_0\rangle$  — continuous spectra in the left and in the right wire respectfully. The corrections are denoted as  $|\gamma_1\rangle, |\varepsilon, L_1\rangle, |\varepsilon, R_1\rangle$ .

It's important to note, that the first order correction for any state is located in the wire opposite to the one hosting the leading order. This can be reflected with spinors in  $LR$ -space as:

$$\Psi_\gamma = \begin{pmatrix} 0 \\ |\gamma_0\rangle \end{pmatrix}_{LR} + \begin{pmatrix} |\gamma_1\rangle \\ 0 \end{pmatrix}_{LR} + \dots \quad (\text{A.1})$$

$$\Psi_R = \begin{pmatrix} 0 \\ |\varepsilon, R_0\rangle \end{pmatrix}_{LR} + \begin{pmatrix} |\varepsilon, R_1\rangle \\ 0 \end{pmatrix}_{LR} + \dots \quad (\text{A.2})$$

$$\Psi_L = \begin{pmatrix} |\varepsilon, L_0\rangle \\ 0 \end{pmatrix}_{LR} + \begin{pmatrix} 0 \\ |\varepsilon, L_1\rangle \end{pmatrix}_{LR} + \dots \quad (\text{A.3})$$

The states are normalized as:

$$\langle\gamma_0|\gamma_0\rangle = 1 \quad \langle\varepsilon, R_0|\varepsilon, R_0\rangle = N_R(\varepsilon) \delta(\varepsilon - \varepsilon) \quad \langle\varepsilon, L_0|\varepsilon, L_0\rangle = N_L(\varepsilon) \delta(\varepsilon - \varepsilon) \quad (\text{A.4})$$

where

$$N_L(\varepsilon) = \frac{4\pi u \sqrt{\varepsilon^2 - g_L^2} (e^{2\kappa_L(\varepsilon)} + 1)^2}{\varepsilon} \quad N_R(\varepsilon) = \frac{4\pi u \sqrt{\varepsilon^2 - g_R^2} (e^{2\eta_R(\varepsilon)} + 1)^2}{\varepsilon} \quad (\text{A.5})$$

Note, that for calculating  $s$ -matrix another normalization, providing  $\langle\varepsilon|v|\varepsilon\rangle = \delta(\varepsilon - \varepsilon)$  should be used, with  $v = u\sigma_z\tau_z$  for long-wave states. The normalization used here serves for computing tunnel Hamiltonian matrix elements.

The definition of the  $\eta_{L,R}$ ,  $\eta_L$  and  $\kappa_R$  is given in the 3.6. The indexes  $L, R$  near the spinors are relate to the wire, where this spinor is present. All the wavefucntions listed here are relevant

for both  $|g_L| < g_R$  and  $|g_L| > g_R$  cases.

The Majorana state is:

$$\langle x | \gamma_0 \rangle = \frac{1}{2} \sqrt{\frac{g_R}{u}} \begin{pmatrix} -1 \\ i \\ -i \\ 1 \end{pmatrix}_R e^{-\frac{g_R x}{u}} \quad (\text{A.6})$$

$$\langle x | \gamma_1 \rangle = \frac{1}{2} \sqrt{\frac{g_R}{u}} \zeta t \left( e^{i\frac{\phi}{2}} + e^{-i\frac{\phi}{2}} \right) \left[ \begin{pmatrix} -i \\ 1 \\ 1 \\ -i \end{pmatrix}_L e^{-\frac{2\Delta x}{u}} - i\zeta \begin{pmatrix} -i \\ -1 \\ 1 \\ i \end{pmatrix}_L e^{-\frac{|g_L|x}{u}} \right] \quad (\text{A.7})$$

Continuous states from the right wire are:

$$\langle x | E, R_0 \rangle = (-ie^{\eta_R(E)} - 1) \begin{pmatrix} -1 \\ -e^{\eta_R(E)} \\ e^{\eta_R(E)} \\ 1 \end{pmatrix}_R e^{-\frac{ix\sqrt{E^2 - g_R^2}}{u}} + (e^{\eta_R(E)} + i) \begin{pmatrix} -e^{\eta_R(E)} \\ -1 \\ 1 \\ e^{\eta_R(E)} \end{pmatrix}_R e^{\frac{ix\sqrt{E^2 - g_R^2}}{u}} \quad (\text{A.8})$$

$$\begin{aligned} \langle x | E R_1 \rangle \Big|_{E < g_L} &= t\zeta (e^{2\eta_R(E)} - 1) \left( e^{i\frac{\phi}{2}} + e^{-i\frac{\phi}{2}} \right) \times \\ &\times \left[ \begin{pmatrix} -i \\ 1 \\ 1 \\ -i \end{pmatrix}_L e^{-\frac{2\Delta x}{u}} - \frac{2i\zeta}{(1 + e^{-i\theta_L(E)})} \begin{pmatrix} -ie^{-i\theta_L(E)} \\ -1 \\ 1 \\ ie^{-i\theta_L(E)} \end{pmatrix}_L e^{\frac{-x\sqrt{g_L^2 - E^2}}{u}} \right] \end{aligned} \quad (\text{A.9})$$

$$\begin{aligned} \langle x | E R_1 \rangle \Big|_{E > g_L} &= t\zeta (e^{2\eta_R(E)} - 1) \left( e^{i\frac{\phi}{2}} + e^{-i\frac{\phi}{2}} \right) \times \\ &\times \left[ \begin{pmatrix} -i \\ 1 \\ 1 \\ -i \end{pmatrix}_L e^{-\frac{2\Delta x}{u}} - \frac{2i\zeta}{(1 + ie^{-\kappa_L(E)})} \begin{pmatrix} e^{-\kappa_L(E)} \\ -1 \\ 1 \\ -e^{-\kappa_L(E)} \end{pmatrix}_L e^{\frac{ix\sqrt{E^2 - g_L^2}}{u}} \right] \end{aligned} \quad (\text{A.10})$$

Continuous states from the left wire are:

$$\langle x | \varepsilon, L_0 \rangle = (e^{\kappa_L(\varepsilon)} - i) \begin{pmatrix} 1 \\ -e^{\kappa_L(\varepsilon)} \\ e^{\kappa_L(\varepsilon)} \\ -1 \end{pmatrix}_L e^{+i \frac{\sqrt{\varepsilon^2 - g_L^2}}{u} x} + (-1 + i e^{\kappa_L(\varepsilon)}) \begin{pmatrix} e^{\kappa_L(\varepsilon)} \\ -1 \\ 1 \\ -e^{\kappa_L(\varepsilon)} \end{pmatrix}_L e^{-i \frac{\sqrt{\varepsilon^2 - g_L^2}}{u} x} \quad (\text{A.11})$$

$$\begin{aligned} \langle x | \varepsilon, L_1 \rangle \Big|_{\varepsilon < g_R} &= \zeta t (e^{2\kappa_L(\varepsilon)} - 1) \left( e^{i\frac{\phi}{2}} + e^{-i\frac{\phi}{2}} \right) \times \\ &\times \left[ \frac{2i\zeta}{(-1 + e^{i\theta_R(\varepsilon)})} \begin{pmatrix} -1 \\ i e^{i\theta_R(\varepsilon)} \\ -i e^{i\theta_R(\varepsilon)} \\ 1 \end{pmatrix}_R e^{-x \frac{\sqrt{g_R^2 - \varepsilon^2}}{u}} + \begin{pmatrix} 1 \\ -i \\ -i \\ 1 \end{pmatrix}_R e^{-\frac{2\Delta x}{u}} \right] \end{aligned} \quad (\text{A.12})$$

$$\begin{aligned} \langle x | \varepsilon, L_1 \rangle \Big|_{\varepsilon > g_R} &= \zeta t (e^{2\kappa_L(\varepsilon)} - 1) \left( e^{i\frac{\phi}{2}} + e^{-i\frac{\phi}{2}} \right) \times \\ &\times \left[ \frac{2it\zeta}{(-1 + i e^{-\eta_R(\varepsilon)})} \begin{pmatrix} -1 \\ -e^{-\eta_R(\varepsilon)} \\ e^{-\eta_R(\varepsilon)} \\ 1 \end{pmatrix}_R e^{\frac{ix \sqrt{E^2 - g_R^2}}{u}} + \begin{pmatrix} 1 \\ -i \\ -i \\ 1 \end{pmatrix}_R e^{-\frac{2\Delta x}{u}} \right] \end{aligned} \quad (\text{A.13})$$

## Appendix B

# Tunnel Hamiltonian derivation

The goal in derivation tunnel Hamiltonian is to make it restoring the corrections of the wavefunctions from appendix A. Recalling, that in  $LR$ -space the Hamiltonian has the form (4.3), we write the unperturbed Green function as:

$$G_0(E) = \frac{1}{E + i0} \begin{pmatrix} 0 & 0 \\ 0 & |\gamma_0\rangle\langle\gamma_0| \end{pmatrix}_{LR} + \int_{g_L}^{\infty} \frac{d\varepsilon}{N_L(\varepsilon)} \frac{1}{E + i0 - \varepsilon} \begin{pmatrix} |\varepsilon, L_0\rangle\langle\varepsilon, L_0| & 0 \\ 0 & 0 \end{pmatrix}_{LR} + \int_{g_l}^{\infty} \frac{d\varepsilon}{N_R(\varepsilon)} \frac{1}{E + i0 - \varepsilon} \begin{pmatrix} 0 & 0 \\ 0 & |\varepsilon, R_0\rangle\langle\varepsilon, R_0| \end{pmatrix}_{LR} \quad (B.1)$$

with  $N_{L,R}$  from (A.5). The corrections for the spinors should be calculated as:

$$\Psi_1(E) = G_0(E) H_T \Psi_0(E) \quad (B.2)$$

So, for different states:

$$|\gamma_1\rangle = \int_{g_L}^{\infty} \frac{d\varepsilon}{N_L(\varepsilon)} \frac{1}{-\varepsilon + i0} |\varepsilon, L_0\rangle \langle\varepsilon, L_0| h_t |\gamma_0\rangle \quad (B.3)$$

$$|E + i0, R_1\rangle = \int_{g_L}^{\infty} \frac{d\varepsilon}{N_L(\varepsilon)} \frac{1}{E - \varepsilon + i0} |\varepsilon, L_0\rangle \langle\varepsilon, L_0| h_t |E R_0\rangle \quad (B.4)$$

$$|E + i0, L_1\rangle = \frac{1}{E + i0} |\gamma_0\rangle \langle\gamma_0| h_t^\dagger |E, L_0\rangle + \int_{g_l}^{\infty} \frac{d\varepsilon}{N_R(\varepsilon)} \frac{1}{E - \varepsilon + i0} |\varepsilon, R_0\rangle \langle\varepsilon, R_0| h_t^\dagger |E, L_0\rangle \quad (B.5)$$

Now, multiplying the third equation by  $\langle\gamma_0|$  and  $\langle\varepsilon, R_0|$ , find:

$$\langle\gamma_0|E + i0, L_1\rangle = \frac{1}{E + i0} \langle\gamma_0| h_t^\dagger |E, L_0\rangle \quad (B.6)$$

$$\langle\varepsilon, R_0|E + i0, L_1\rangle = \frac{1}{E - \varepsilon + i0} \langle\varepsilon, R_0| h_t^\dagger |E, L_0\rangle \quad (B.7)$$

The l.h.s. of this equation can be calculated with the help of appendix A. After doing so, we arrive to the result (4.5).

## Appendix C

# Multiphoton ionization

This appendix is focused on high-order perturbation theory, ionization rates in particular.

### C.1 Basics about Green's functions

The starting point is the general setup of a discrete bound state subject to a weak and slow perturbation  $V(t)$ . The bound state energy is zero. The goal is to obtain the ionization rate. The time evolution of the wave function obeys the Schroedinger equation:

$$i \frac{\partial}{\partial t} \Psi = (H_0 + V) \Psi \quad (\text{C.1})$$

In the absence of perturbations, the solution is  $\Psi(t) = \Psi_0$  (since  $E_0 = 0$  it is literally time-independent). For further analysis it's convenient to consider the unperturbed retarded Green's function  $G^R(E)$  defined so that:

$$G^R(E)(E + i0 - H_0) = 1 \quad (\text{C.2})$$

If the bound state is normalized,  $\langle \gamma | \gamma \rangle = 1$  and the continuous spectrum is normalized according to  $\langle E | E' \rangle = N(E) \delta(E - E')$  with some reasonably nice  $N(E)$  then:

$$\mathbb{I} = |\gamma\rangle\langle\gamma| + \int \frac{|E\rangle\langle E|}{N(E)} dE \quad (\text{C.3})$$

Similarly,  $H_0$  and  $G^R$  in the energy representation:

$$H_0 = \int \frac{|E\rangle\langle E|}{N(E)} E dE \quad G^R(\epsilon) = \frac{|\gamma\rangle\langle\gamma|}{\epsilon + i0} + \int \frac{|E\rangle\langle E|}{(\epsilon + i0 - E)N(E)} dE \quad (\text{C.4})$$

Integrals over  $E$  include all states in the continuous spectrum. Where the latter is degenerate, a summation over the degenerate states must be carried out. From now on the "R" index for retarded Green's function will be omitted.

In time representation the Green's function obeys:

$$\left(i\frac{\partial}{\partial t_2} - H_0\right) G(t_2, t_1) = \delta(t_2 - t_1) \quad (\text{C.5})$$

One can formally introduce the Green's function in energy representation with two arguments as a Fourier-transform of  $G(t_2, t_1)$ :

$$G(E_2, E_1) = \iint e^{iE_2 t_2 - iE_1 t_1} G(t_2, t_1) dt_1 dt_2 \quad (\text{C.6})$$

As  $H_0$  is time independent,  $G(t_2, t_1) = G(t_2 - t_1, 0)$ , so:

$$G(E_2, E_1) = 2\pi\delta(E_2 - E_1) G(E_1) \quad (\text{C.7})$$

One can also find, that for any eigenstate  $|E_0\rangle$

$$G(t) |E_0\rangle = -ie^{-iE_0 t} \theta_H(t) |E_0\rangle \quad (\text{C.8})$$

With the help of Green's function the Schroedinger equation (C.1) can be solved as:

$$\begin{aligned} \Psi(t) = \Psi_0 + \int G_0(t - t') V(t') \Psi_0(t') dt' + \\ \iint G_0(t - t') V(t') G_0(t' - t'') V(t'') \Psi_0(t'') dt' dt'' + \dots \end{aligned} \quad (\text{C.9})$$

where the  $\Psi_0$  is unperturbed wavefunction. This equation can be rewritten by the introduction

## C.2 Fermi Golden Rule (first order)

Consider first the lowest order to the Fermi Golden rule by only keeping the linear term in  $V$ . Let the Fourier decomposition of  $V$  be:

$$V(t) = \sum_n V_n e^{-i\omega_n t} \quad (\text{C.10})$$

(Hermiticity demands  $V(t) = V(t)^*$  so that  $V_n = V_{-n}^*$ ). Suppose there is an unperturbed continuous spectrum parameterized by  $E$ , with  $\langle E|E'\rangle = f(E)\delta(E - E')$ . The first step is to calculate

$\langle E|\Psi(t)\rangle$ , i.e. the quantum amplitude of being in state  $|E\rangle$  at time  $t$ . It is:

$$\begin{aligned}
\langle E|\Psi(t)\rangle &= \langle E|\int G_0(t-t')V(t')\Psi_0(t')dt'\rangle = \int \langle E|G_0(t-t')V(t')|\Psi_0\rangle dt' = \\
&= \int \int \langle E|G_0(t-t')|E'\rangle \langle E'|V(t')|\Psi_0\rangle dt' \frac{dE'}{N(E)} \\
&= \int e^{-i(t-t')E} \theta_H(t-t') \langle E|V(t')|\Psi_0\rangle dt' = \\
&= e^{-iEt} \sum_n \int e^{it'(E-\omega_n)} \theta_H(t-t') \langle E|V_n|\Psi_0\rangle dt' \quad (C.11)
\end{aligned}$$

Assuming that the perturbation was turned on at  $t' = 0$  the integral over  $t'$  is taken from  $t_0$  to  $t$  and gives:

$$\langle E|\Psi(t)\rangle = e^{-iEt} \sum_n \langle E|V_n|\Psi_0\rangle \frac{e^{it(E-\omega_n)} - 1}{i(E-\omega_n)} \quad (C.12)$$

Thus, the probability density of being in the state  $|E\rangle$  is (omit all frequencies except the resonant one should be omitted since the contributions from non-resonant frequencies can be neglected at long times):

$$\rho(E) = |\langle E|V_n|\Psi_0\rangle|^2 \frac{4 \sin^2 \frac{t(E-\omega_n)}{2}}{(E-\omega_n)^2} \quad (C.13)$$

so that the probability of being in a state between  $E$  and  $E + \delta E$  is at large times:

$$\begin{aligned}
P(E + \delta E, E) &= |\langle E|V_n|\Psi_0\rangle|^2 \int_E^{E+\delta E} \frac{dE}{N(E)} \frac{4 \sin^2 \frac{t(E-\omega_n)}{2}}{(E-\omega_n)^2} = \\
&= 2t |\langle E|V_n|\Psi_0\rangle|^2 \int_E^{E+\delta E} \frac{d(tE/2)}{N(E)} \frac{4 \sin^2 \frac{t(E-\omega_n)}{2}}{t^2 (E-\omega_n)^2} = \\
&= 2t |\langle E|V_n|\Psi_0\rangle|^2 \frac{\pi}{N(E)} \theta_H(\omega_n - E) \theta_H(E + \delta E - \omega_n) \quad (C.14)
\end{aligned}$$

In other words, the probability density at large  $t$  behaves exactly like the  $\delta$ -function:

$$\rho(E) = 2\pi |\langle E|V_n|\Psi_0\rangle|^2 \delta(E - \omega_n) \quad (C.15)$$

which is the well-known Fermi Golden rule. (Note, that the probability is  $dP = \rho(E)dE/f(E)$  – do not forget the normalization). Thus, the ionization rate (i.e.  $P/t$ ) for a single photon is expressed

as:

$$\mathcal{I} = \frac{2\pi |\langle E | V_n | \Psi_0 \rangle|^2}{f(E)} \quad (\text{C.16})$$

### C.3 Fermi Golden Rule (high order)

To treat the higher-order perturbation theory it's convenient to rewrite (C.9) as:

$$\Psi(t) = \Psi_0 + \int \int G_0(t - t') W(t', t'') \Psi_0(t'') dt' dt'' \quad (\text{C.17})$$

where  $W$  incorporates all powers of perturbation theory:

$$W = V + V G_0 V + V G_0 V G_0 V + \dots \quad (\text{C.18})$$

The perturbation  $V$  in energy space is:

$$\begin{aligned} V(E', E) &\equiv \int V(t', t) e^{it'E' - iEt} dt' dt = \int V(t) e^{i(E' - E)t} dt = \\ &= \sum_n V_n \int e^{i(E' - E - \omega_n)t} dt = \sum_n V_n 2\pi \delta(E' - E - \omega_n) \end{aligned} \quad (\text{C.19})$$

The second term of the perturbation theory  $W_2 = V G V$  in energy representation reads:

$$\begin{aligned} W_2(E_2, E_1) &= \int V(E_2, E) G_0(E, E') V(E', E_1) \frac{dE dE'}{(2\pi)^2} = \\ &= \sum_{nm} 2\pi \delta(E_2 - E_1 - \omega_n - \omega_m) V_n G_0(E_1 + \omega_m) V_m \end{aligned} \quad (\text{C.20})$$

Very similarly, the  $N$ -th-order term is:

$$W_N(E_2, E_1) = \sum_{n_1, \dots, n_N} 2\pi \delta \left( E_2 - E_1 - \sum_{i=1}^N \omega_{n_i} \right) V_{n_N} \prod_{j=1}^{N-1} G_0 \left( E_1 + \sum_{s=1}^j \omega_{n_s} \right) V_{n_j} \quad (\text{C.21})$$

The above expression sums over all processes involving  $N$  photons. Note how the Green's functions contains the cumulative energy of all photons absorbed by the time. The  $\delta$ -function at the start of the expression indicates that the energy is changed by  $\sum \omega_{n_i}$ . It makes more sense to sort processes within  $W$  not by photon count  $N$  but rather by the total energy gained, since the total ionization rate should be dominated by ionization to the lowest accessible continuum state.

Defining this activation energy as  $\mathcal{E}$ , write:

$$W_{\mathcal{E}}(E_2, E_1) = 2\pi\delta(E_2 - E_1 - \mathcal{E})w_{\mathcal{E}}(E_1) \quad (\text{C.22})$$

$$w_{\mathcal{E}}(E) = \sum_{\{n_i\}:\mathcal{E}} V_{n_N} \prod_{j=1}^{N-1} G_0 \left( E + \sum_{s=1}^j \omega_{n_s} \right) V_{n_j} \quad (\text{C.23})$$

The summation is over all sets of photons  $n_i$  that total an energy of  $\mathcal{E}$ , i.e. such sets that  $\sum_i^N \omega_{n_i} = \mathcal{E}$ . The photon number  $N$  itself depends on the particular photon set  $n_i$ . The total composite perturbation  $W$  can be written as a sum of  $W_{\mathcal{E}}$  with different  $\mathcal{E}$ . However, only one term is relevant — the one with  $\mathcal{E} = \min |g_L|, |g_L|$ . (If the elementary frequency quantum  $\omega$  is large enough, this is replaced by the lowest  $\mathcal{E}$  that surpasses the minimum gap).

Now the Fermi Golden rule result (C.16) can be rederived for  $W_{\mathcal{E}}$ . It's easy to see that  $W$  has the same energy structure as the single-photon perturbation  $V$ . Both operators simply shift the energy. Thus, one may simply put  $W_{\mathcal{E}}$  into the Fermi Golden rule instead of  $V$  to get the full-theory results:

$$\mathcal{I} = \frac{2\pi |\langle \mathcal{E} | w_{\mathcal{E}} | \Psi_0 \rangle|^2}{N(\mathcal{E})} \quad (\text{C.24})$$

Thus to find the ionization rate one should calculate  $w_{\mathcal{E}}$  from (C.23).
